Coulomb-excitation programme at UWC

The Coulomb-excitation process with the combination of highly-efficient γ and particle detector systems present a great tool to study quadrupole collectivity in nuclei and probing nuclear-structure properties. This process employs the well-known Coulomb interaction and selectively excites collective nuclear states which decay back to the ground state through γ -ray transitions. Coulomb-excitation measurements have been carried out by the UWC Coulex group, where various reorientation-effect Coulomb-excitation measurements (RECE) have recently been carried out for a systematic study throughout nuclei in the sd shell. This work reports on our new measurements on $Q_S(2_1^+)$ values at iThemba LABS and TRIUMF on (^{12}C , ^{20}Ne , ^{32}S , ^{36}Ar and ^{40}Ar), which will be presented during this conference. In particular, a solution is proposed for the striking zig-zag pattern of $Q_S(2_1^+)$ values observed at the end of the sd shell.
