

The X-rays detecting system of the FAMU Experiment for the measurement of the muon transfer rate to carbon

TIPP 2023 Conference

04-09 September 2023

Simone Monzani
For the FAMU analysis team
Università di Udine

Outline

- Motivation
- The FAMU Experiment
- The X-rays detecting system
- Performances
- Measurement of the transfer rate from μp to carbon
- Conclusions

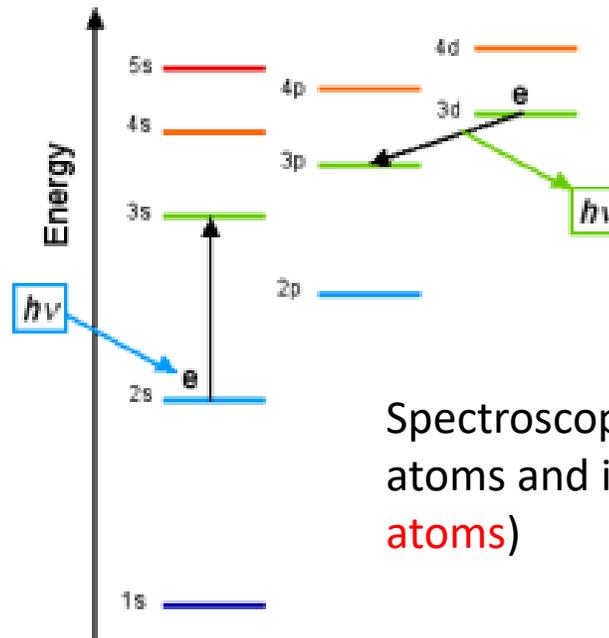

FAMU: Fisica degli Atomi Muonici (Physics with muonic atoms)

Fundamental physics: the properties of the proton

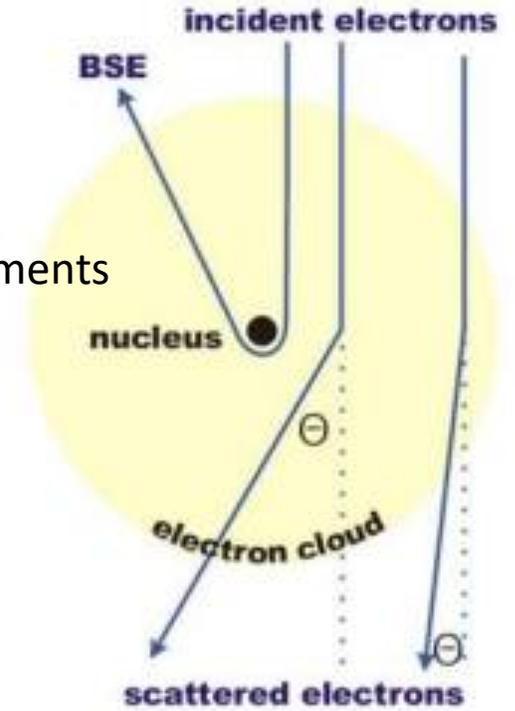

FAMU target: hyperfine splitting (HFS) of muonic hydrogen ground level

the Zemach radius of the proton

scattering (electron experiments and elastic muon-proton)

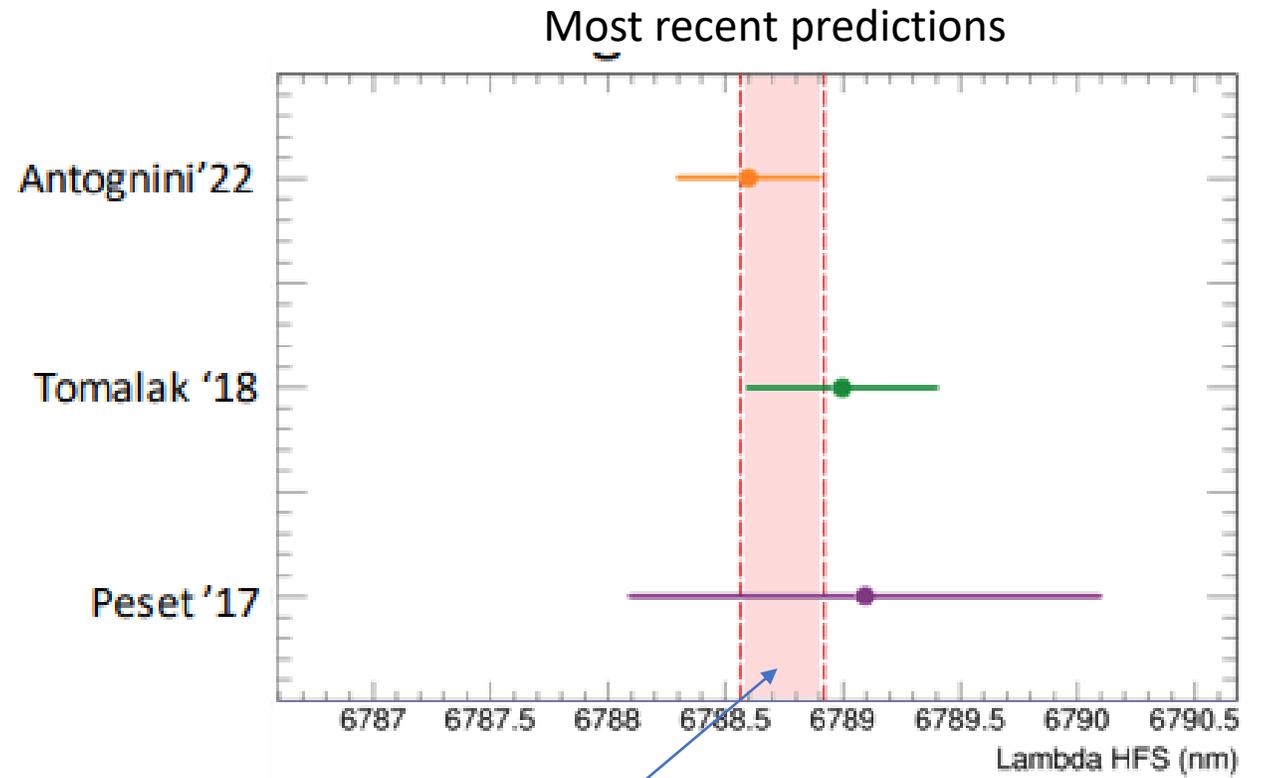

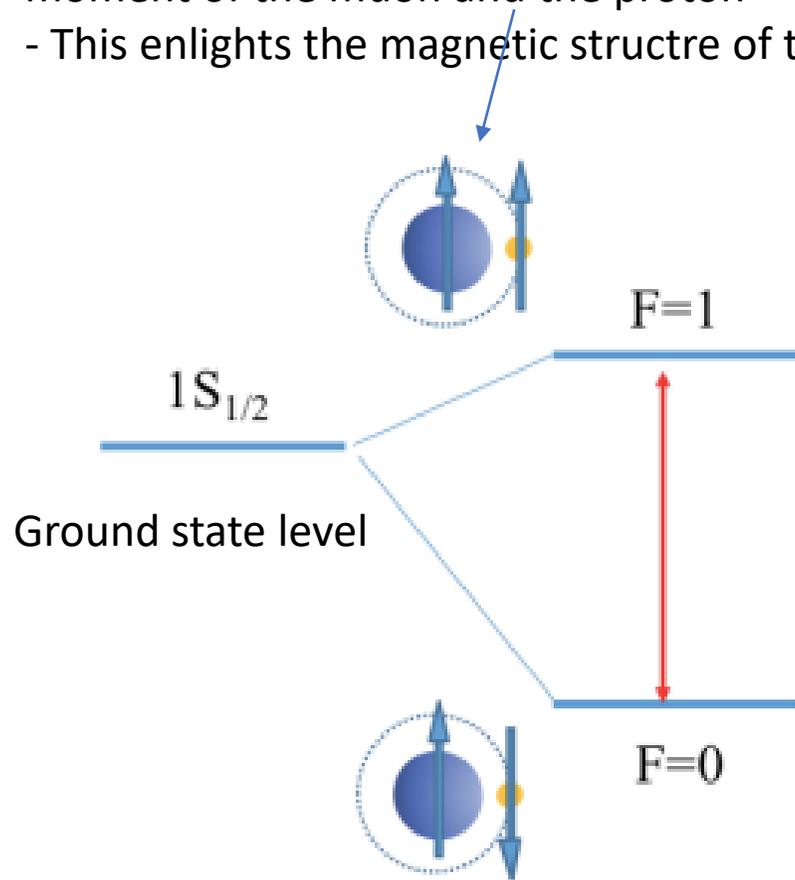

Spectroscopy (electronic atoms and ions, **exotic atoms**)

FAMU: Fisica degli Atomi Muonici (Physics with muonic atoms)

- HFS comes from the interaction between the magnetic moment of the muon and the proton
- This enlightens the magnetic structure of the proton

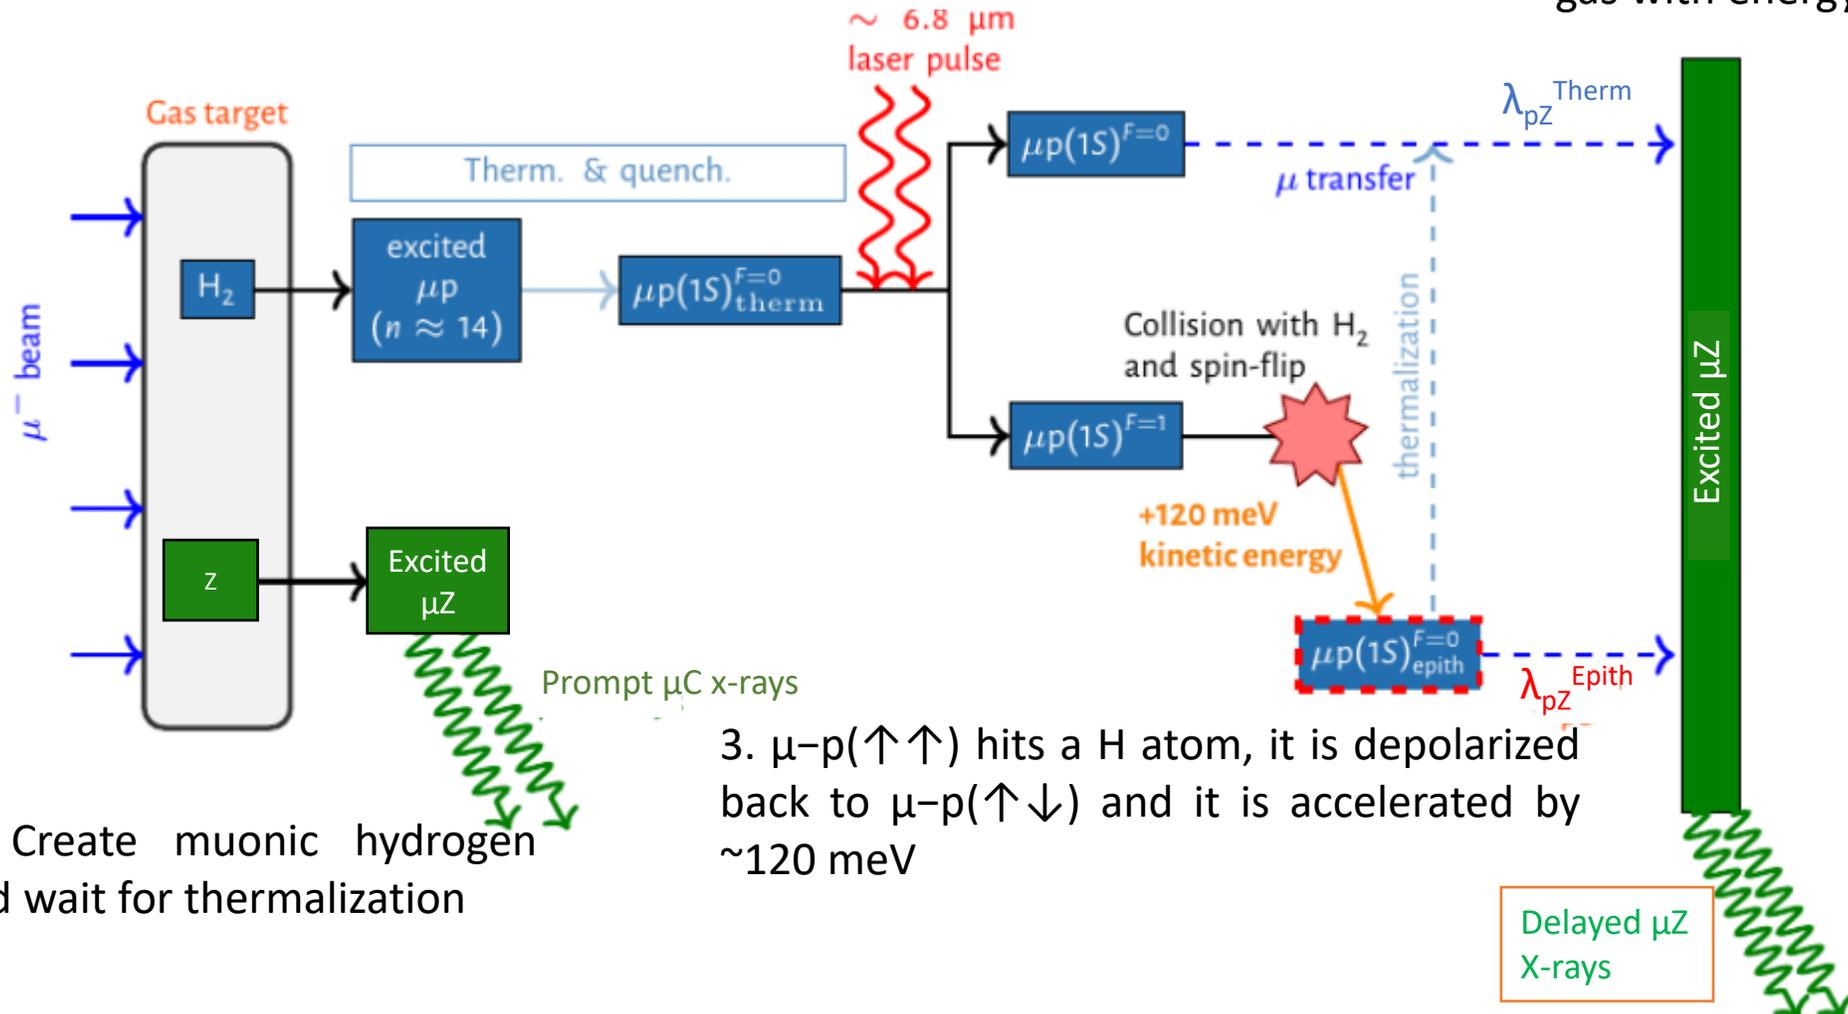

Target range of 20 days of data taking (0.36 nm centered in the weighted mean of the 3 measurements)

FAMU method and workflow

2. Shoot laser at resonance of μp from 1^1S_0 to 1^3S_1 :
 $\mu p(\uparrow\downarrow) \rightarrow \mu p(\uparrow\uparrow)$

4. μ^- are transferred to heavier gas with energy-dependent rate

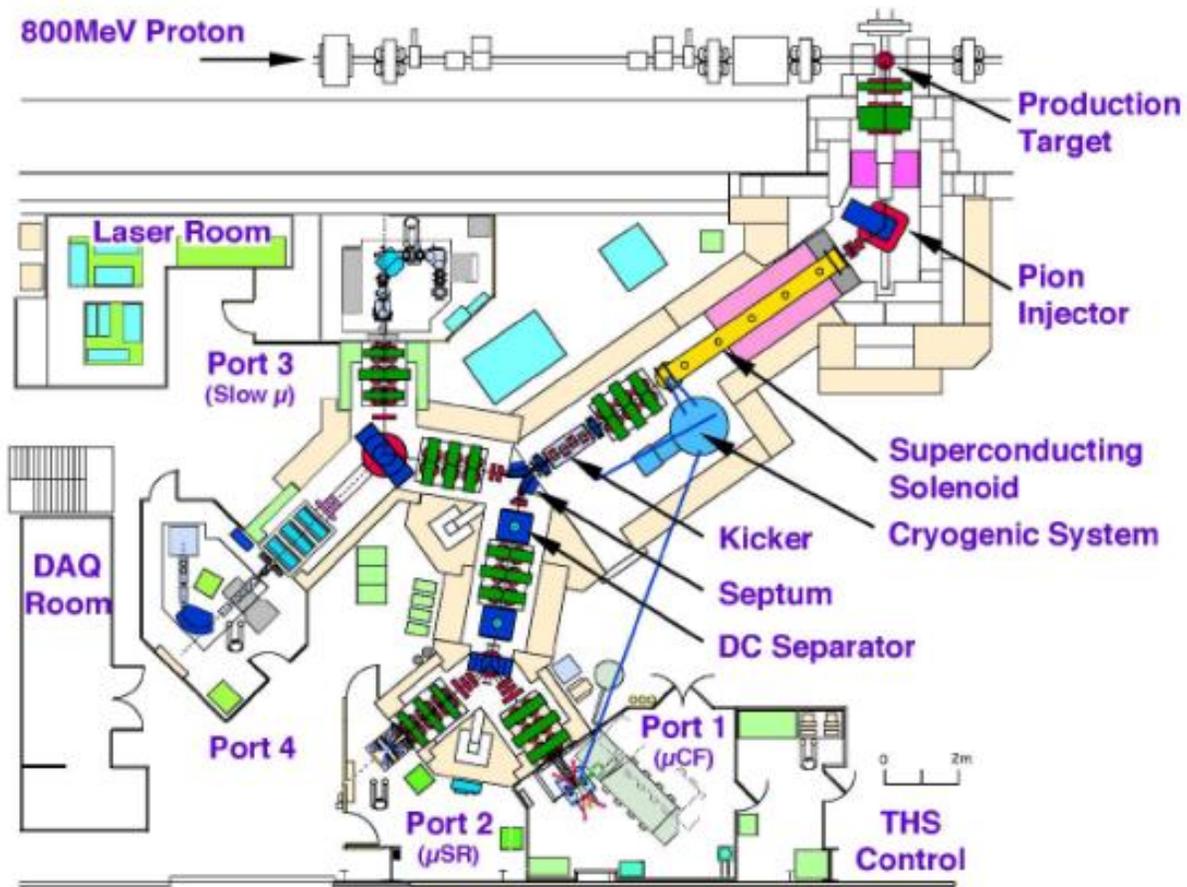

1. Create muonic hydrogen and wait for thermalization

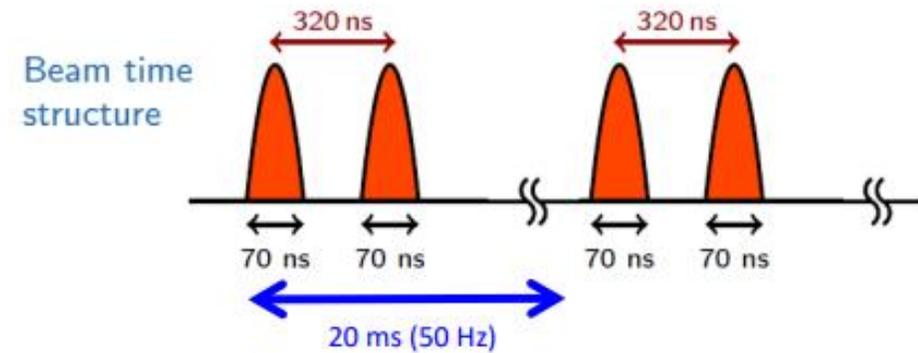

3. $\mu p(\uparrow\uparrow)$ hits a H atom, it is depolarized back to $\mu p(\uparrow\downarrow)$ and it is accelerated by ~ 120 meV

5. λ_0 resonance: maximization of the time distribution of μ^- transferred events

RIKEN RAL facility

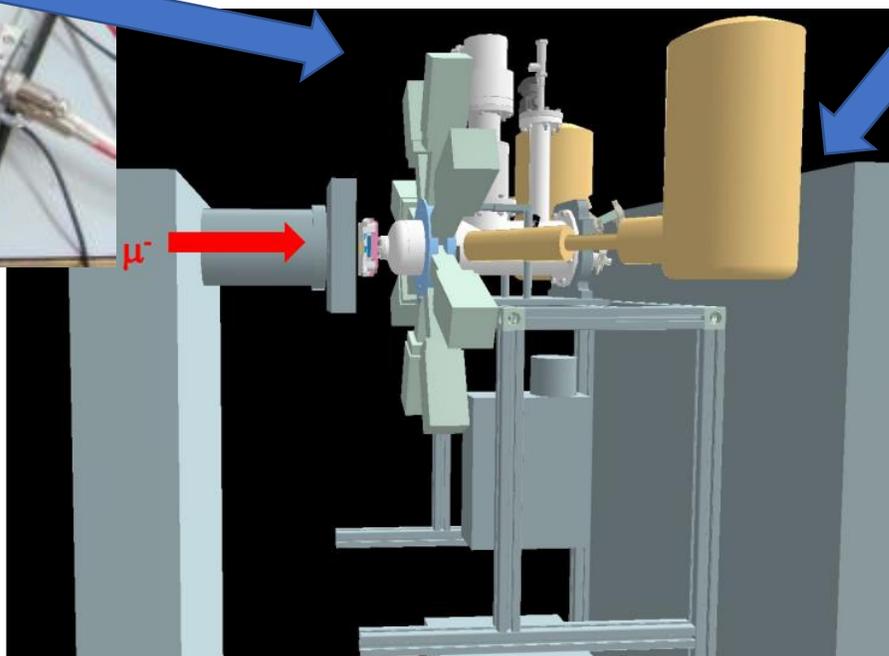

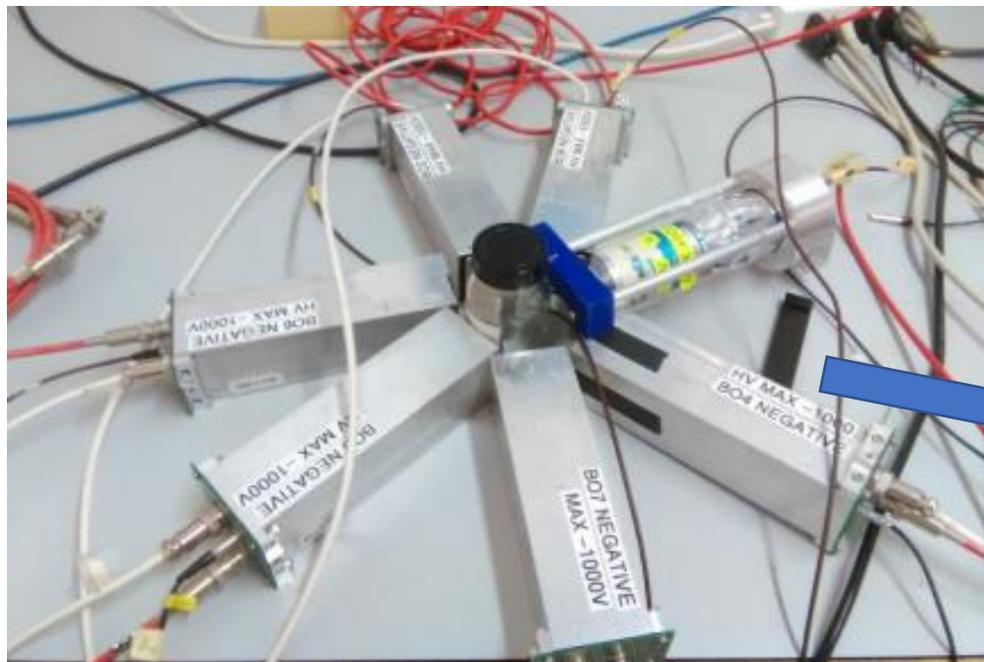

UK - Didcot

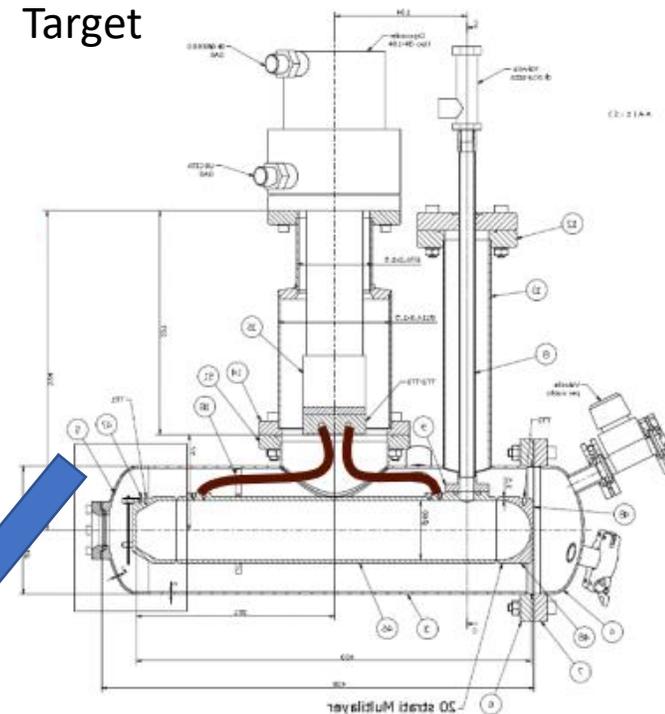

Rutherford Appleton Laboratory – Oxfordshire UK
The brightest pulsed muon beam facility in the world

Experimental setup

LaBr3(Ce): fast timing X-rays detectors

Target

Gas: $\text{H}_2 + \text{CH}_4$ (0.3%) at different temperatures

7 detectors are available,
placed around the gas target

- read by PMTs
- fast electronics and fast digital processing signal available
- 360° covered

The X-rays detection system

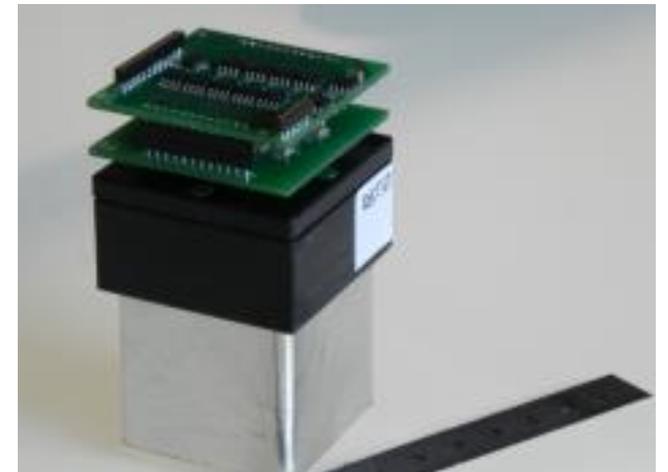

LaBr₃(Ce): fast timing X-rays detectors

- up to 3-5% energy resolution (multiple X-rays and electrons are generated due to the muon interaction with matter);
- up to 500 ps timing resolution (the transfer mechanism from μ hydrogen to the carbon occurs in hundreds of nanoseconds);
- small signal duration (to avoid pile-up);
- to be as linear as possible in pulsed high rate conditions;
- high efficiency in the 50-200 keV energy range (signal region);
- cover a large solid angle (X-rays emission by the target is isotropic);
- good over time stability.

Photomultiplier (PMT) guarantees the timing specification preserving the energy resolution and it can be used in high rate applications.

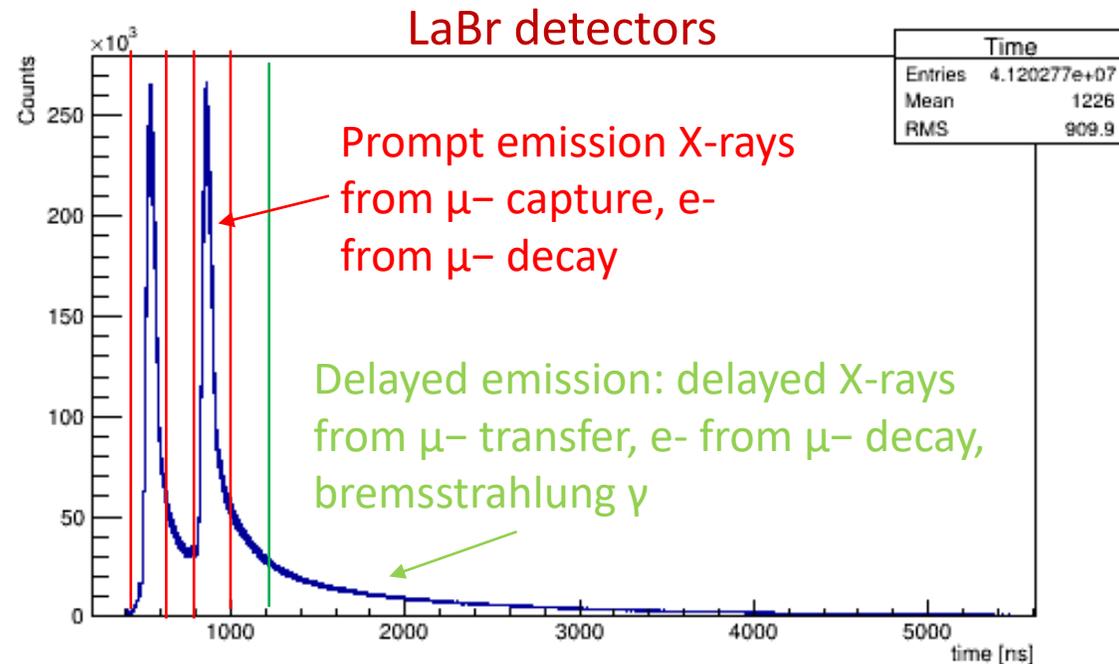

2.5 x 2.5 cm (diameter x thickness)
cylindrical shape

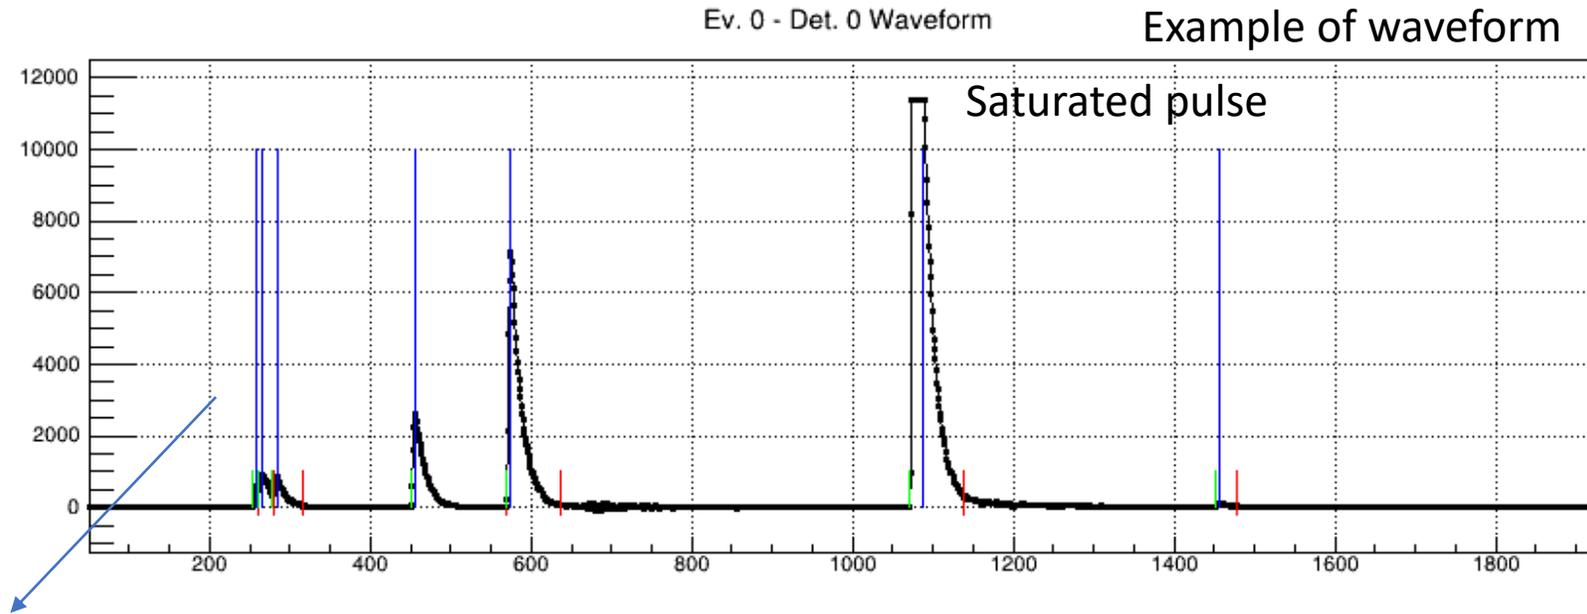

crystals coupled with HAMAMATSU
R11265U-200 PMT

Acquisition method

At each trigger we acquire a window of 10 microsecond
Produce μ 's and wait for their **thermalization** (about 150 ns)
Study the time evolution of **Carbon X rays** in the delayed region
for extracting the transfer rate to carbon

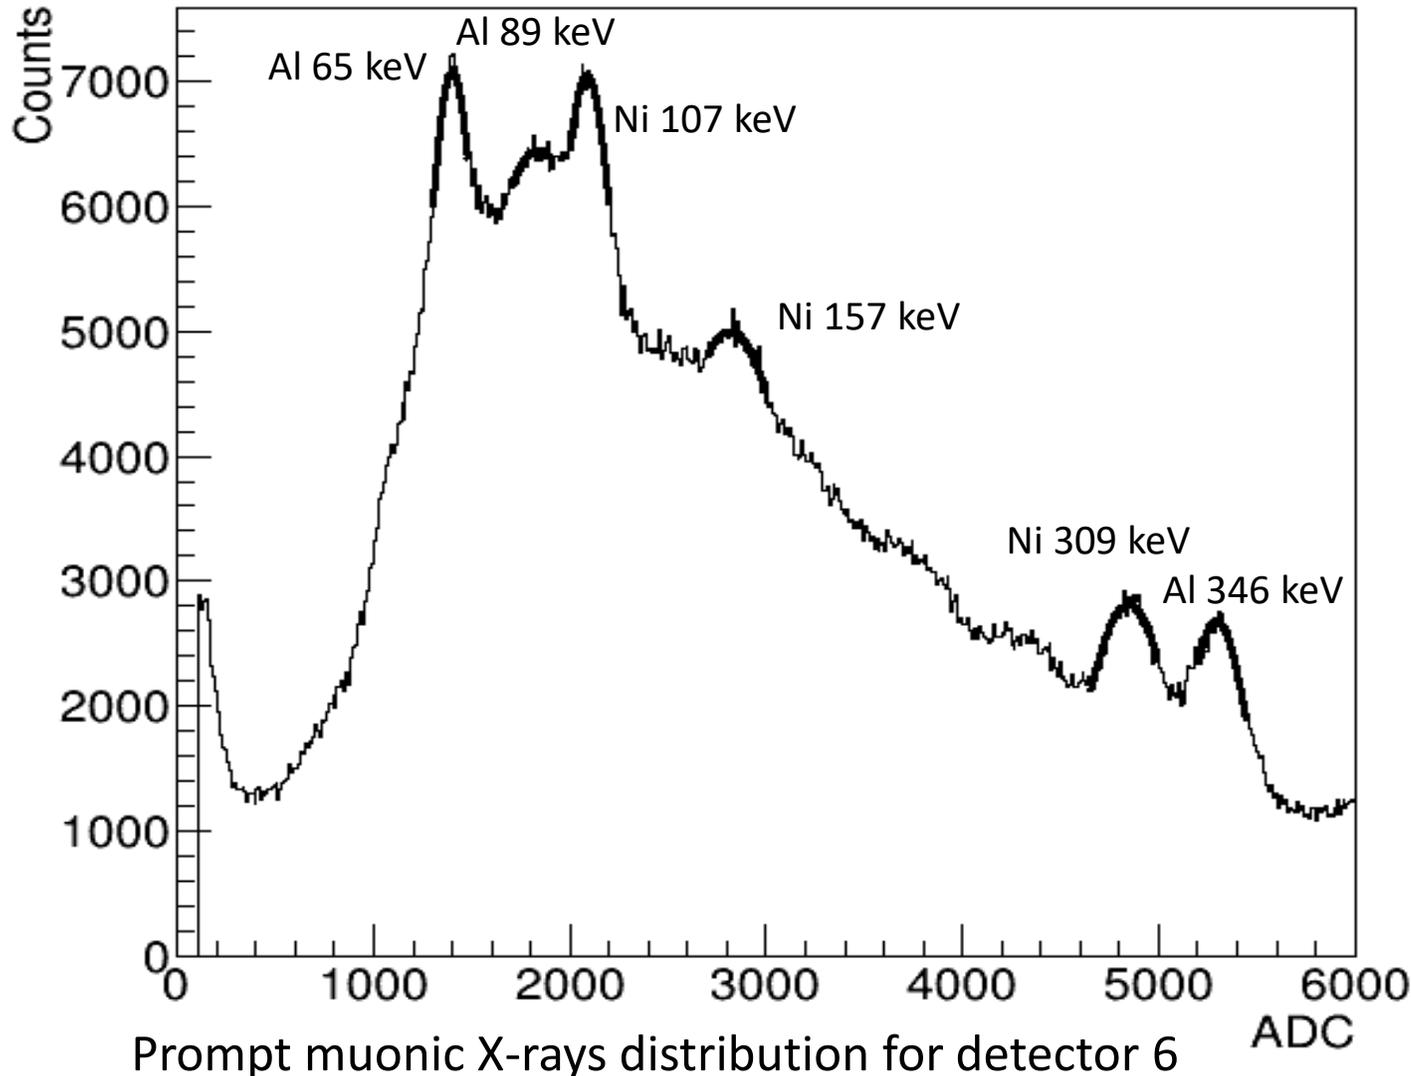

Detectors waveform

For the signal amplitude detector signals are fitted and the preliminary cut is done through the study of the derivative of the waveform

- Rise time is very fast equal to 10 ns
- Decay time is around 30 ns
- Baseline is constant in time and no relevant background is present
- No undershoot is present
- Pile-up is solved modeling the single pulses with Landau functions

Prompt muonic X-rays distribution

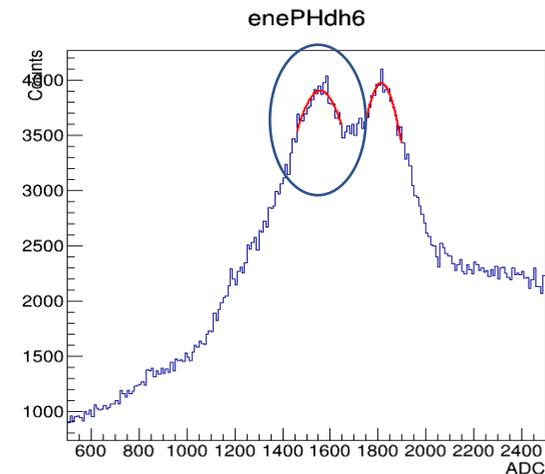

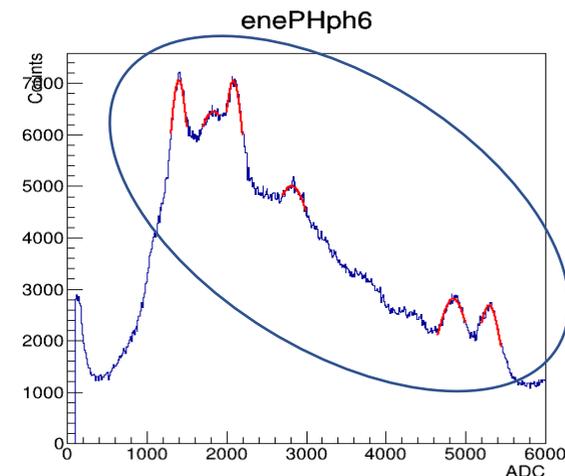

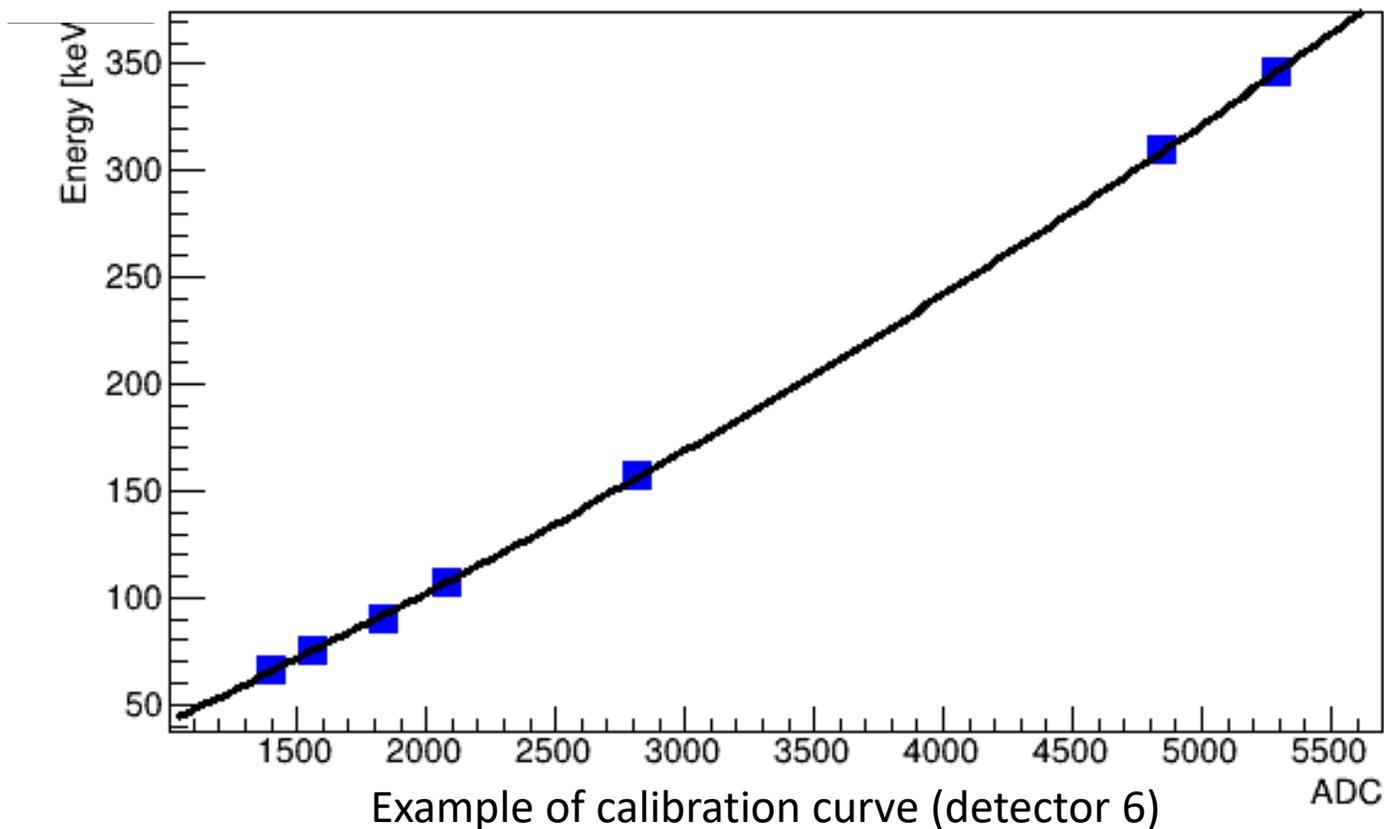

- Selection cuts were applied to clean the sample
- 6 emission lines are clearly visible
- Aluminium and Nickel are well evident and used for the detector calibration
- The single fit is converging in all the detectors
- Resolution ranges between 10 and 30%
- Increasing slope at low energy is due to the muon spill
- Background is mainly due to Bremsstrahlung

Energy calibration curve

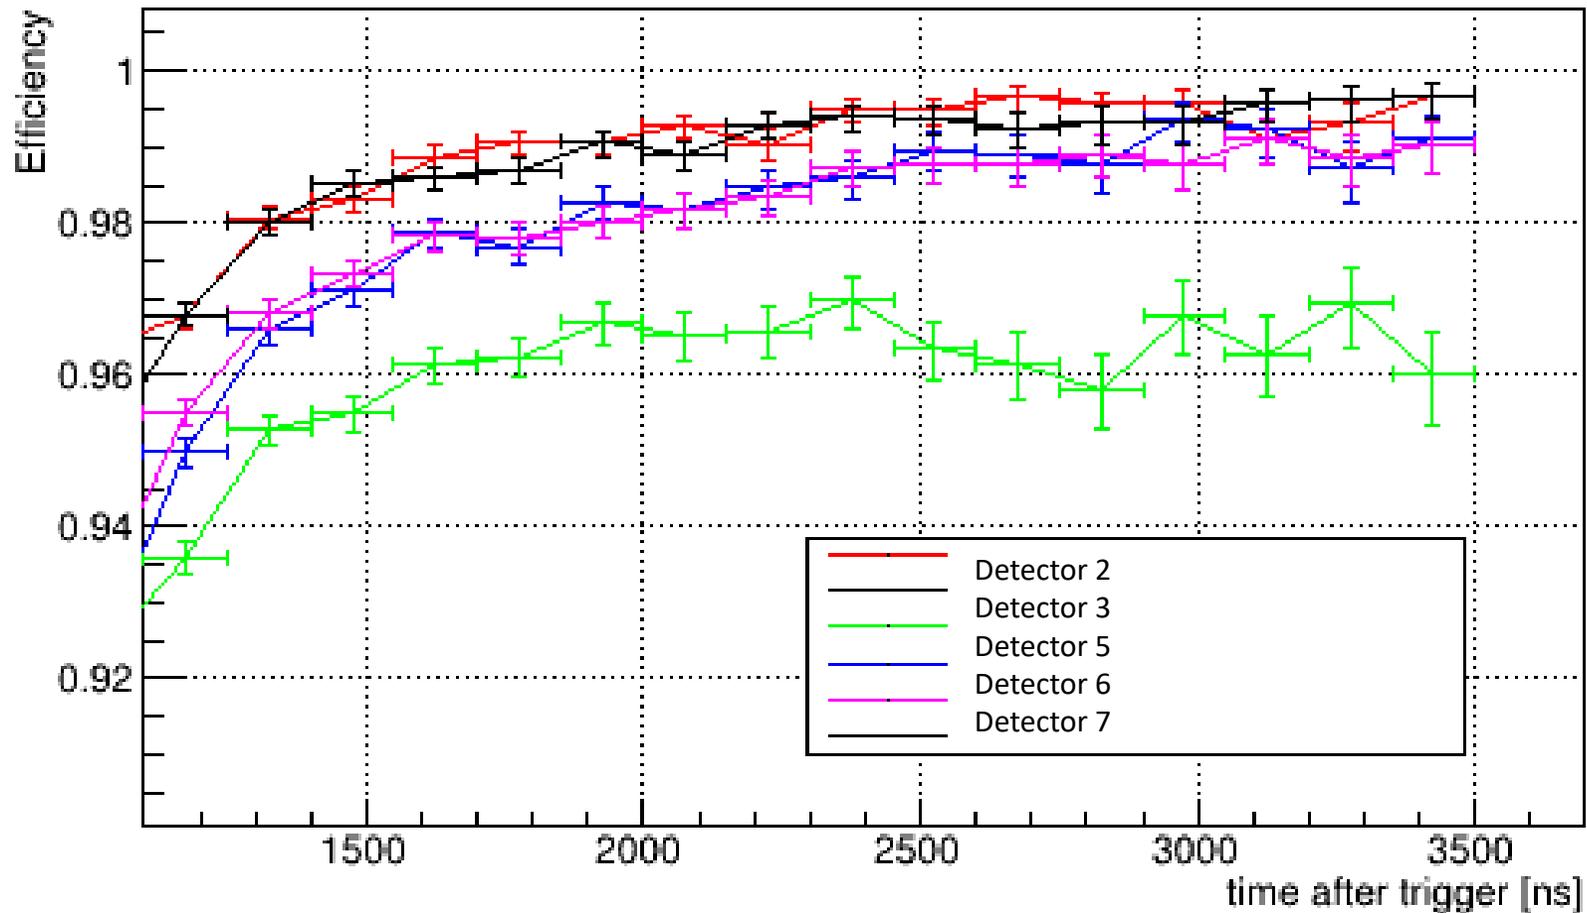

- Single fit applied on prompt and delayed signal, error has been estimated as the variation of the mean value of the fit in different ADC ranges
- Higher density of points in our region of interest

LaBr6

Efficiency

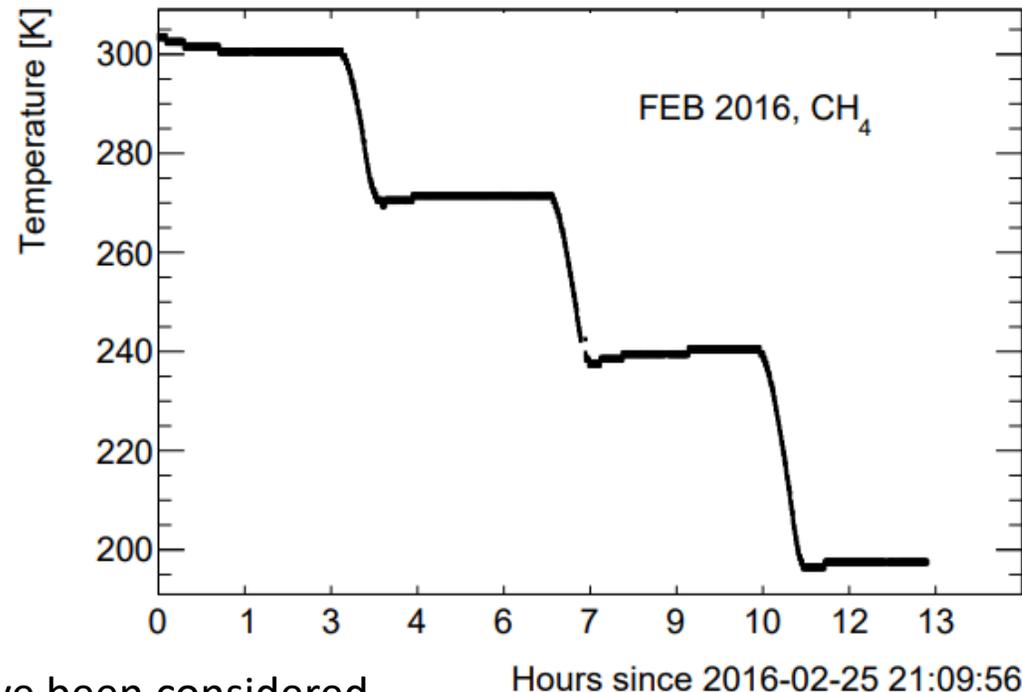

Efficiency always higher than 95% for all detectors in the time region selected for extracting the transfer rate to carbon

Muon transfer rate to carbon

Transfer rate measured with different temperatures

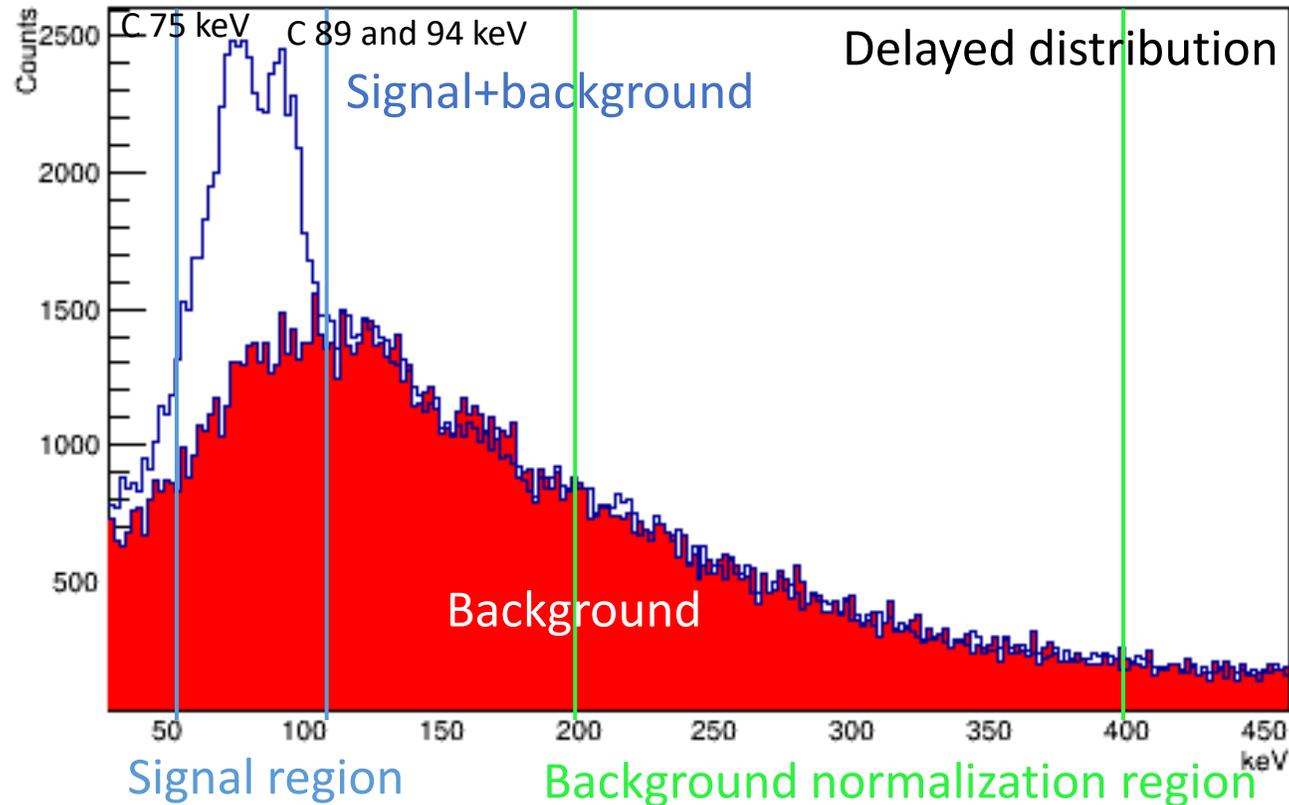

- Hydrogen and CH₄ gas mixture, with a nominal concentration of CH₄ equal to 0.3%
- Gradual cooling down from room temperature (300 K) to 197 K
- 197 K is the lowest limit in order to avoid condensation

4 temperatures have been considered

Example of signal and background at 197 K

Example from all detectors in a time between 1552 and 1691 ns after trigger

- Signal is well visible confirming the high performances of the X-rays detecting system
- Distributions are corrected by efficiency and livetime
- Resolution of the k_{α} ranges between 25% and 40% (acceptable considering the low energy region and similar to the low energy prompt ones)
- Background is estimated from the hydrogen only sample

Carbon X-rays per time interval

$$dN_{\mu p}(t) = S(t)dt - N_{\mu p}\lambda_{dis}dt$$

μ decay rate (p-bound)

$$\lambda_{dis} = \lambda_0 + \varphi(c_p\lambda_{pp\mu} + c_D\lambda_{pD} + c_C\lambda_{pC})$$

Gas density in LHD units
($4.25 \cdot 10^{22}$ atoms cm^3)

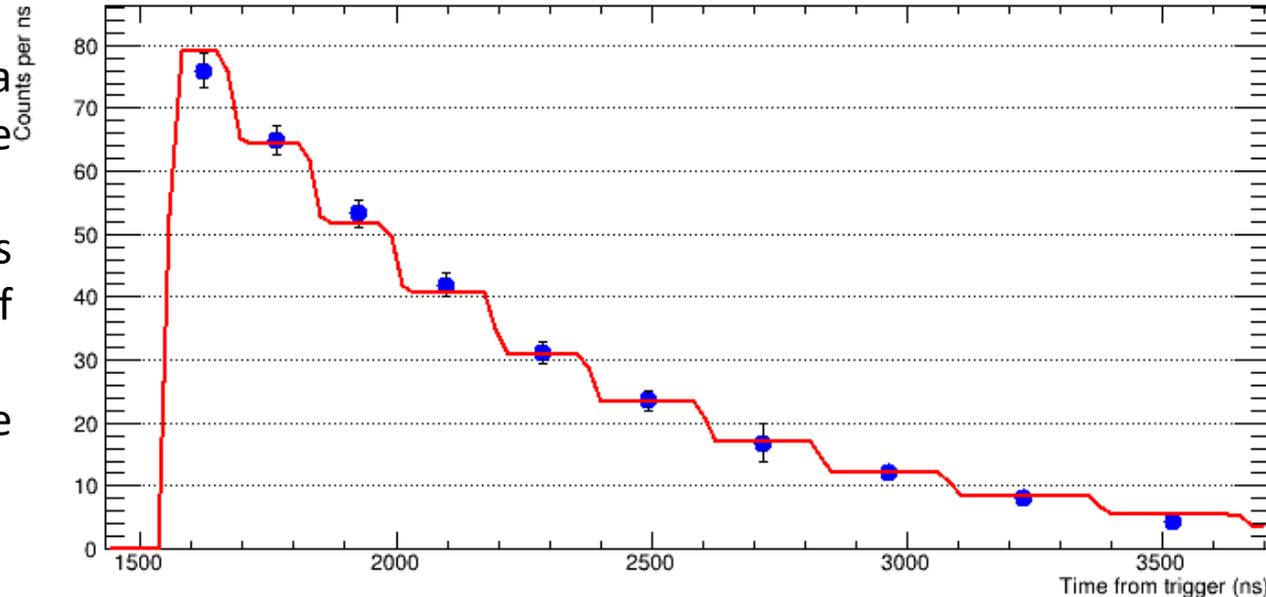

Rate of formation of $pp\mu$

μ transfer rate to deuterium

transfer rate to carbon

Measurement at 300 K

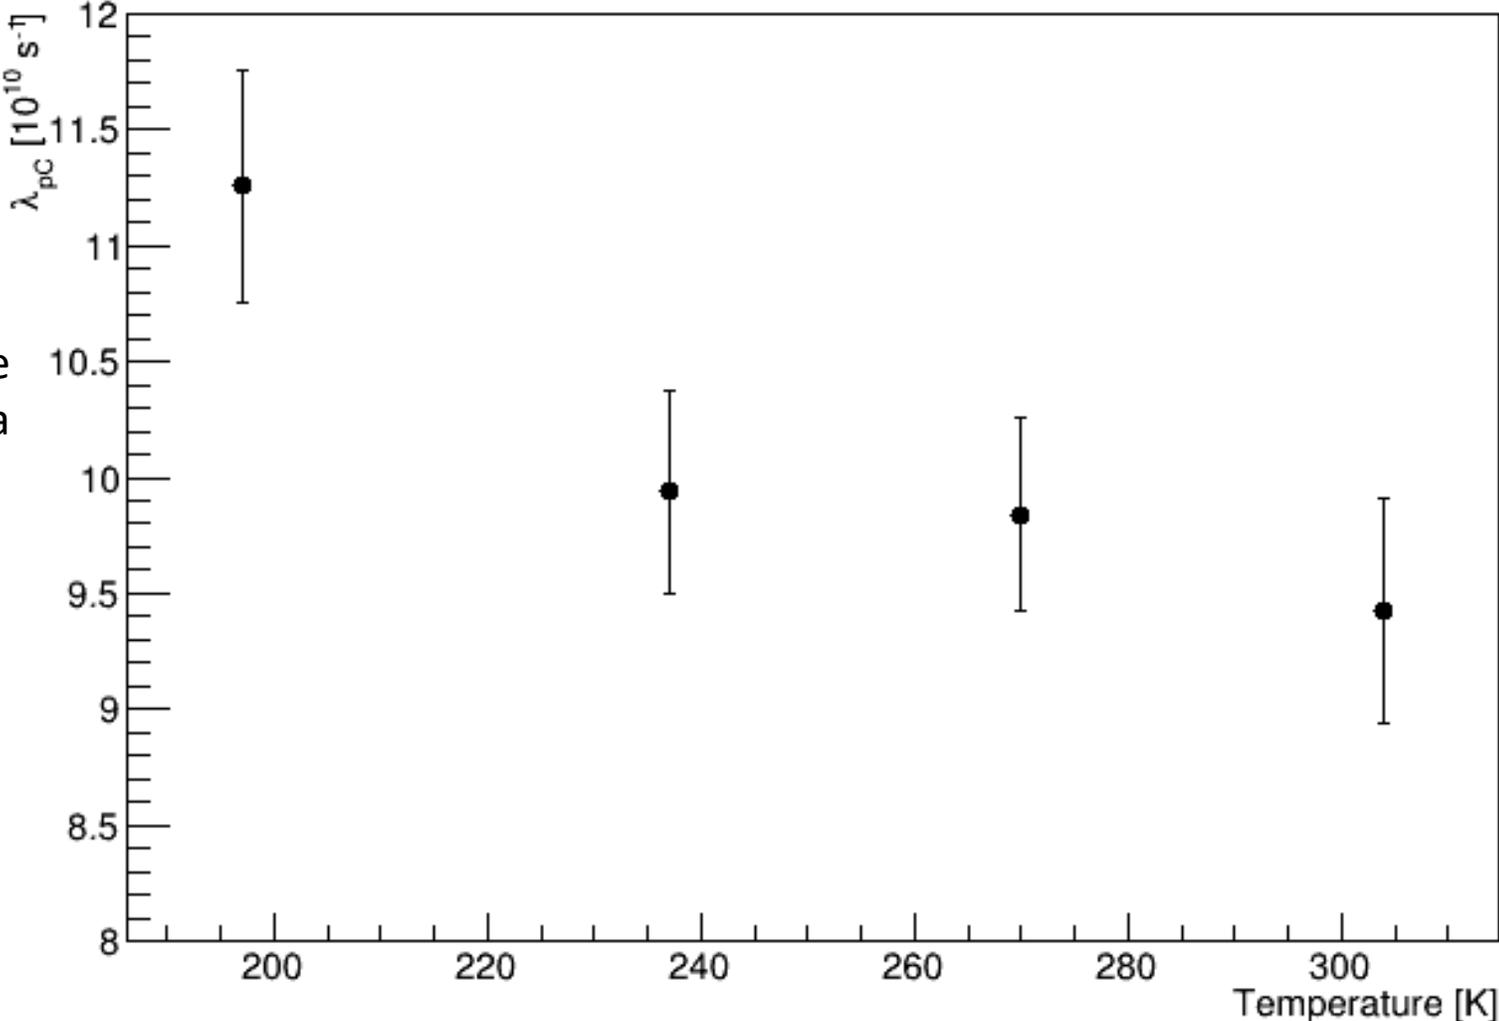

- Also a linear binning with a different number of bins have been tested
- Consistency check of results show that the optimal choice of time threshold is 1500
- The best starting time value have been defined as around 1500 ns

chi/ndf=0.495639

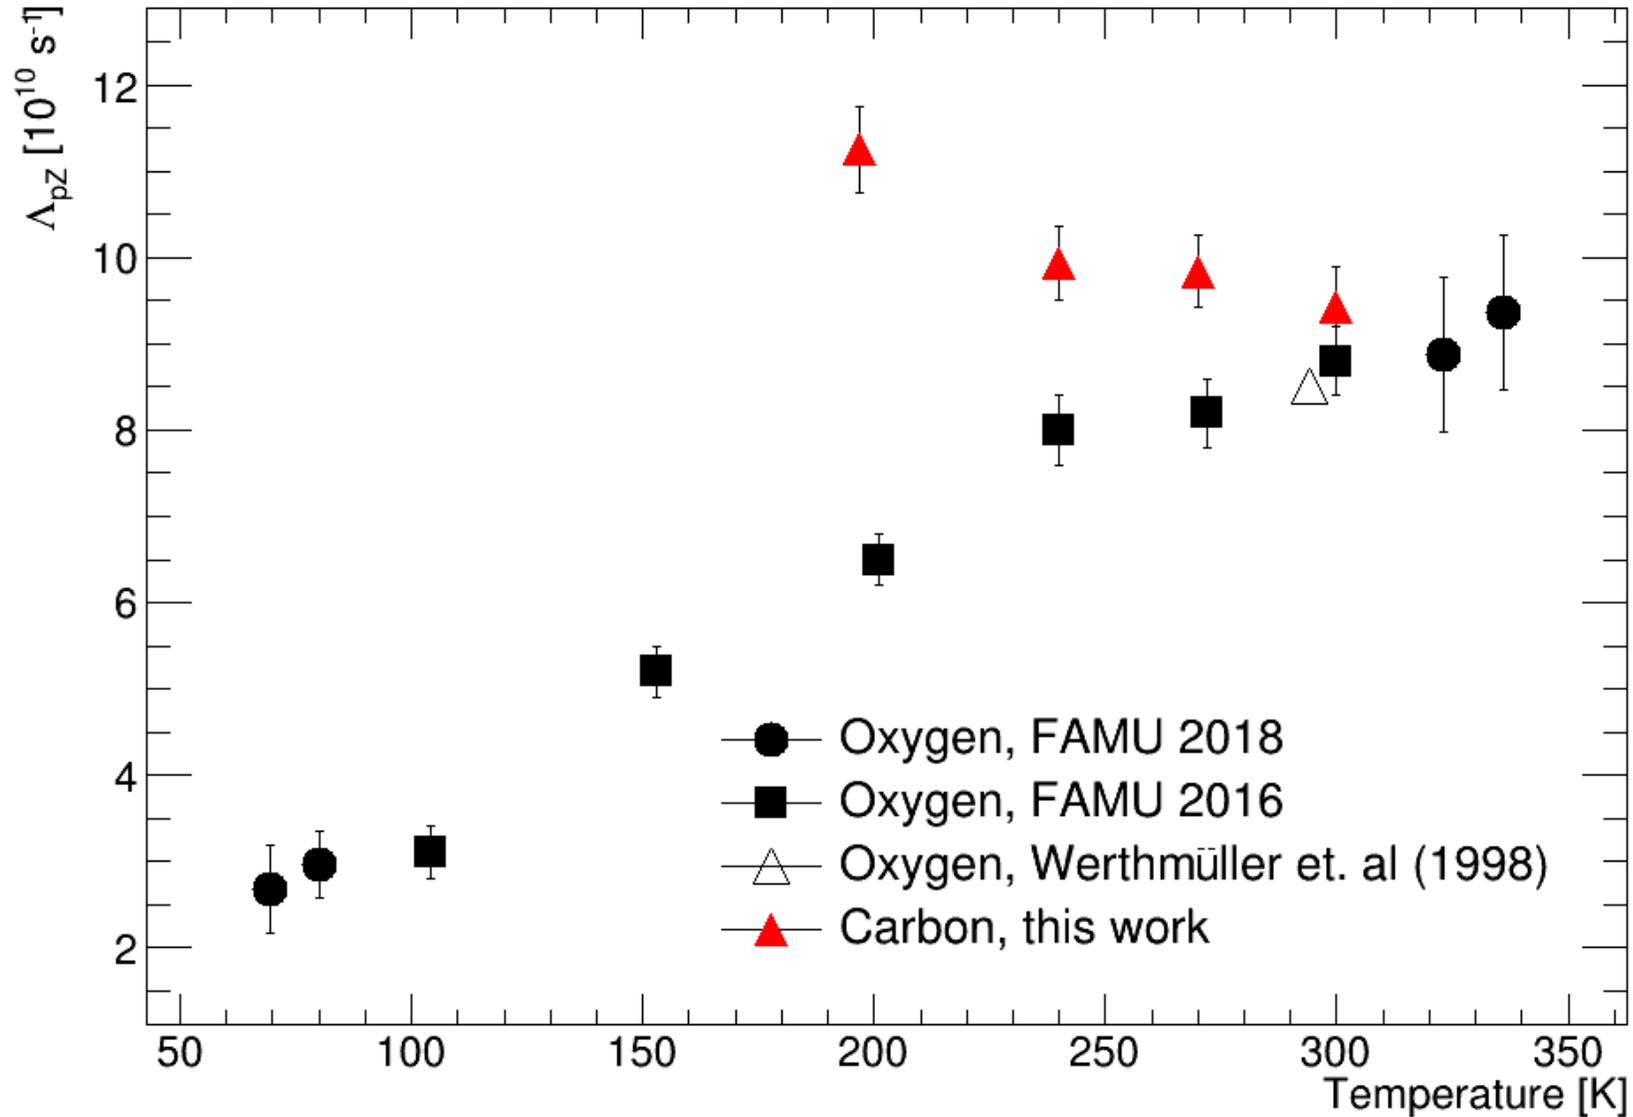

Carbon transfer rate as a function of temperature

Carbon transfer rate

Results are compatible with a constant and a linear fit.

Carbon and oxygen transfer rate temperature

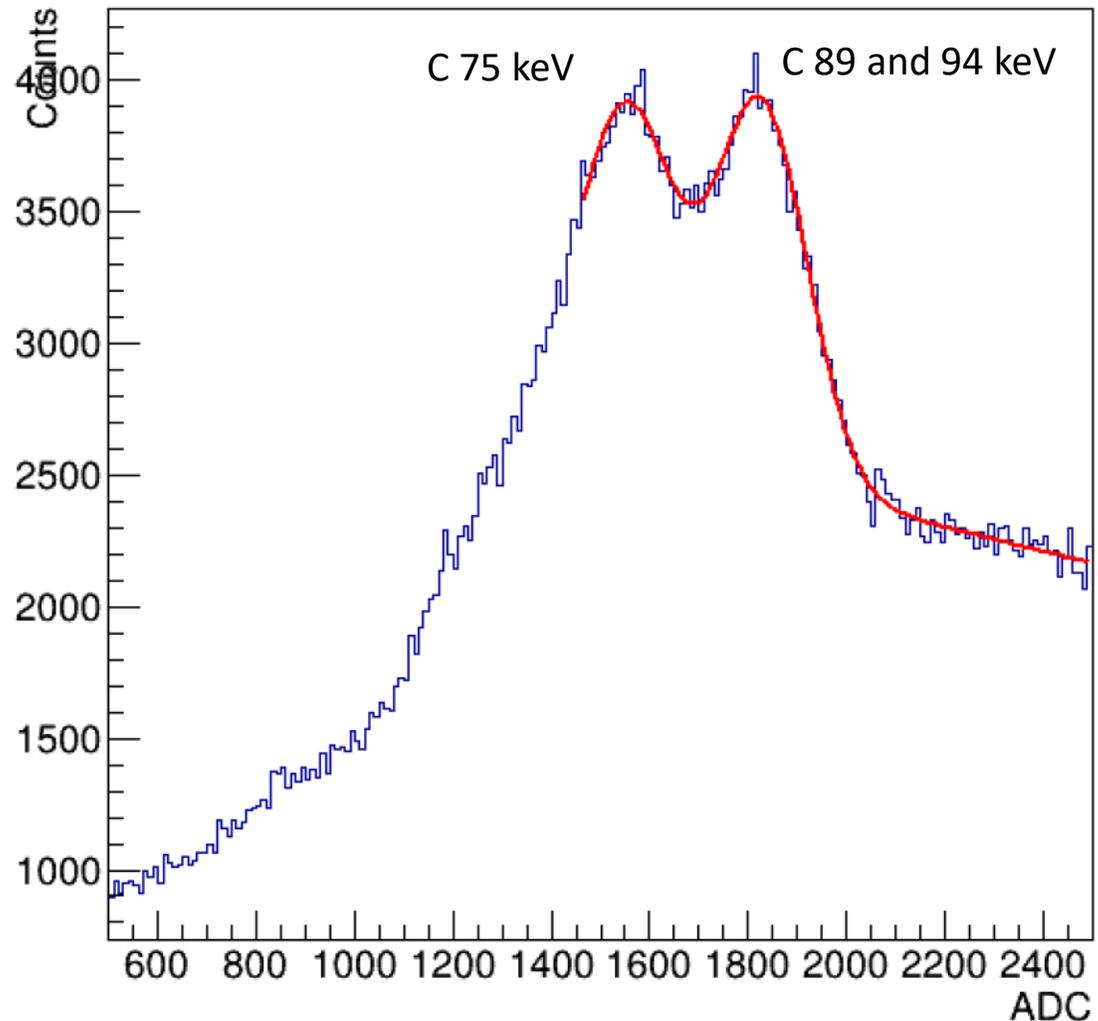

Conclusions

- This recent result confirms the fitness of the detection system in the pulsed intense muon beam;
- Prompt and delayed signals are clear with enough accuracy and precision to be suitable for a fine calibration
- The LaBr technology show an efficiency higher than 95% and a livetime higher than 99% in the whole signal region
- The detector high performances let the measurement of the carbon signal well evident above the background
- This allows us to measure the carbon transfer rate and to compare it with the previous results for oxygen;
- New Data taking on progress with laser and an improvement of this technology for the determination of the HF splitting.

Back-up

Energy distribution

Delayed distribution for detector 6

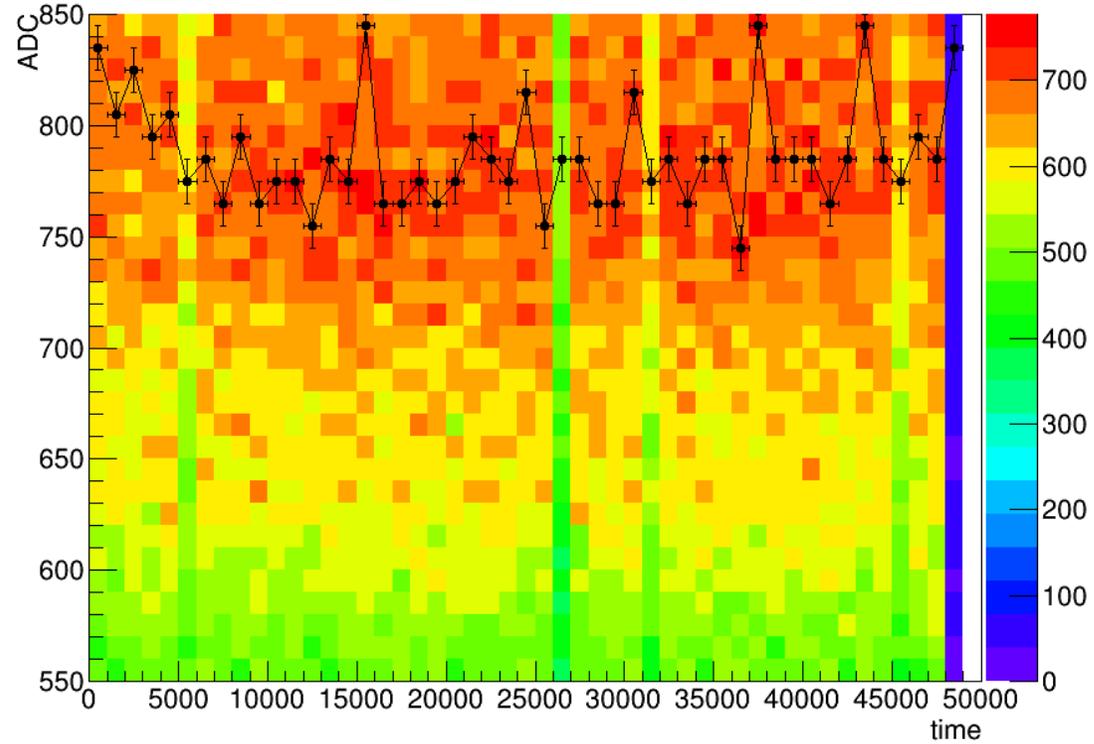

10 logarithmic time after trigger intervals

- 1552<t<1691
 - 1691<t<1844
 - 1844<t<2009
 - 2009<t<2190
 - 2190<t<2387
 - 2387<t<2601
 - 2601<t<2835
 - 2835<t<3089
 - 3089<t<3367
 - 3367<t<3670
-
- Gaussian+exponential fit around the transition energies
 - The exponential fit is not fundamental

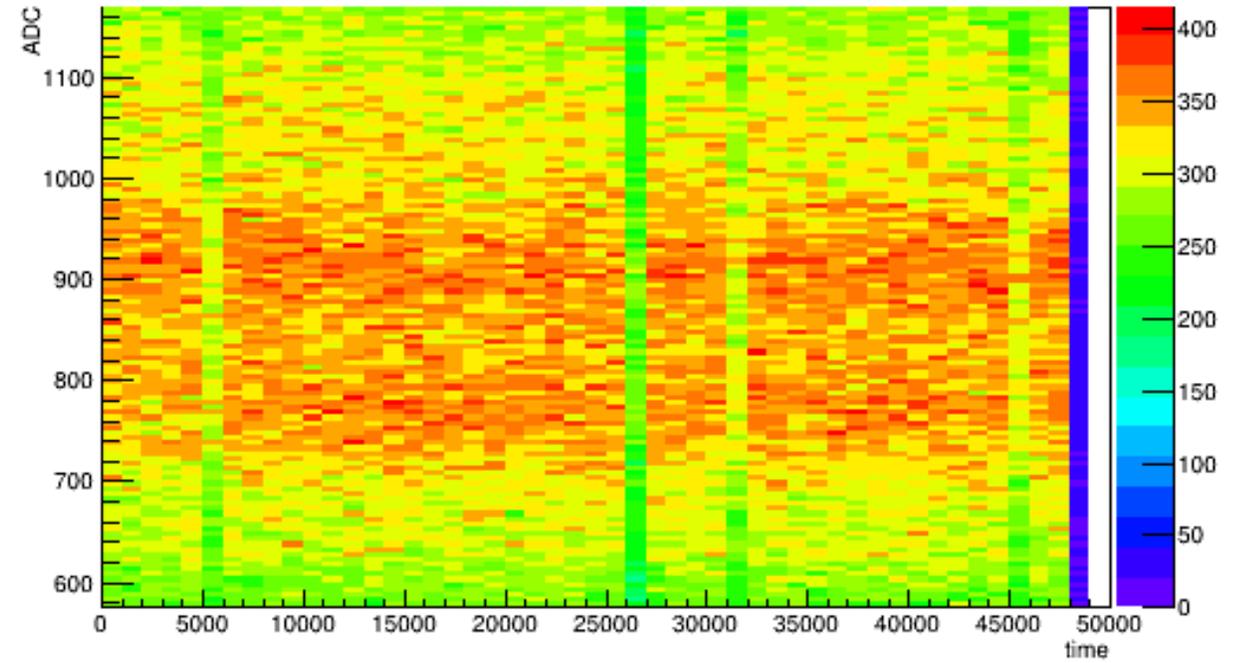

Time dependency

C 75 keV, to check the time dependency with all detectors

ADCTimeD

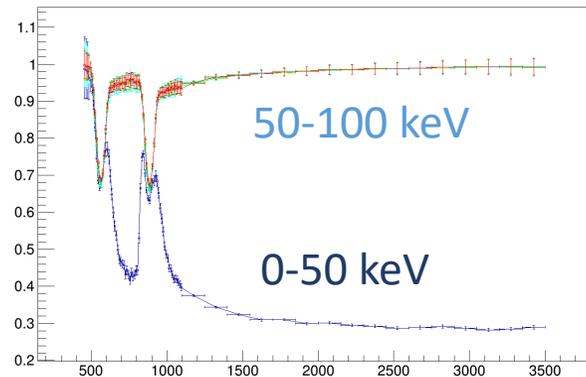

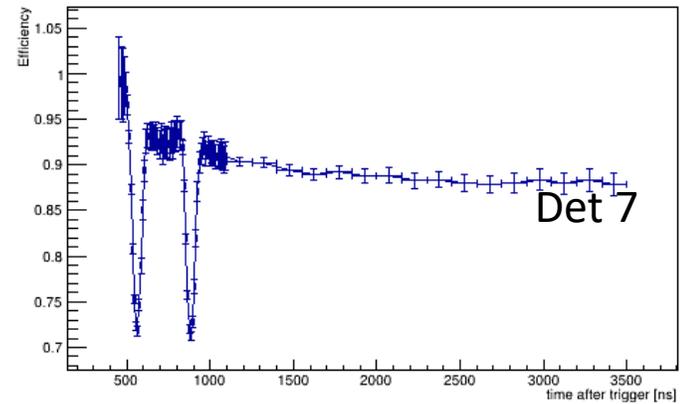

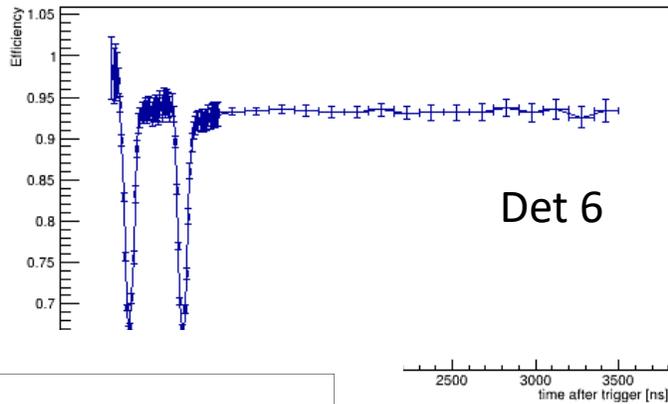

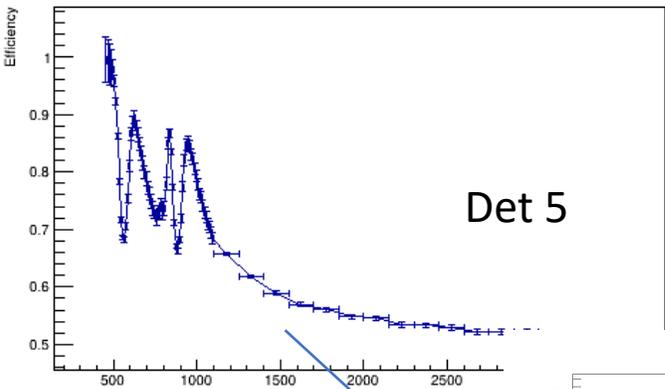

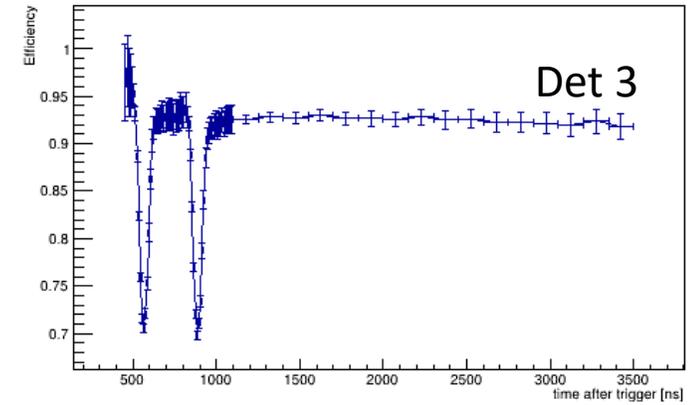

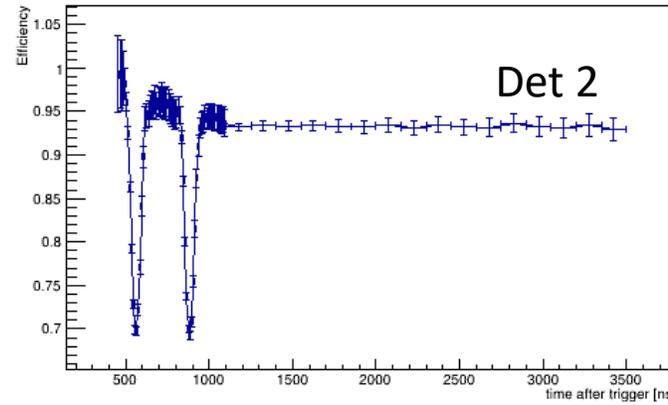

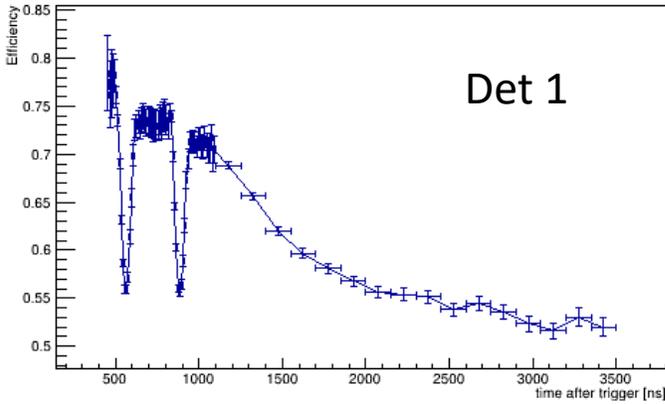

ADCTimeD

Efficiency

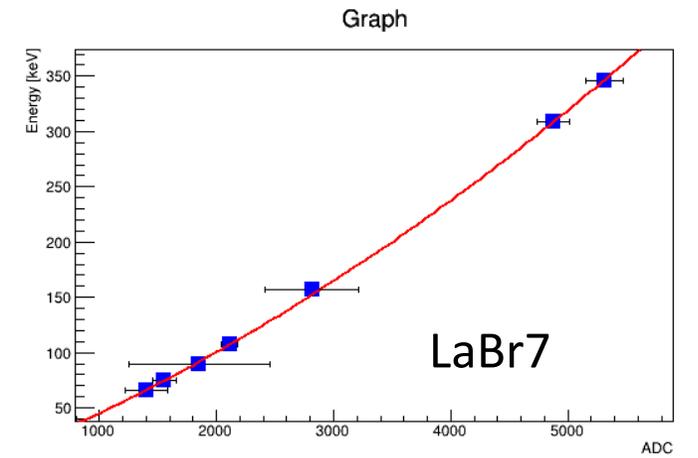

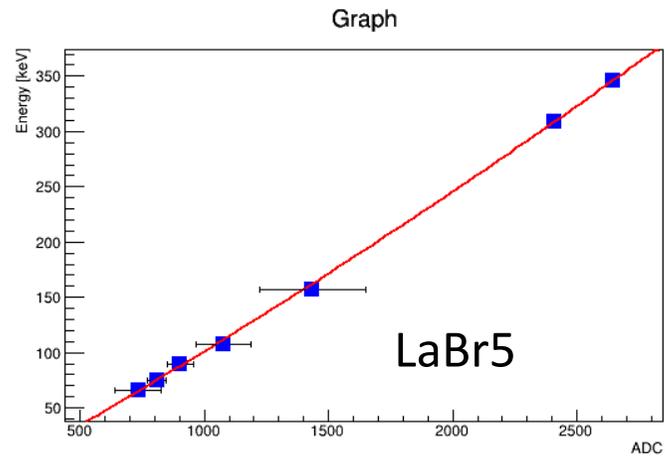

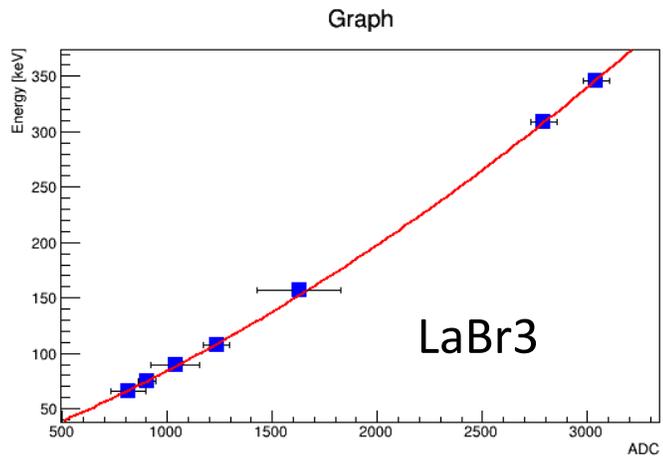

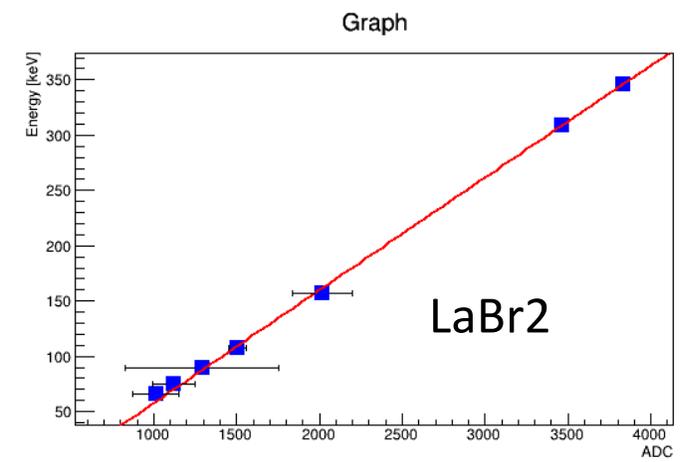

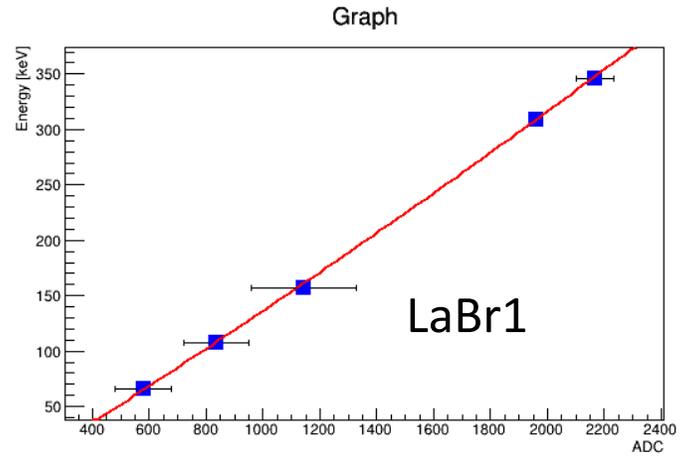

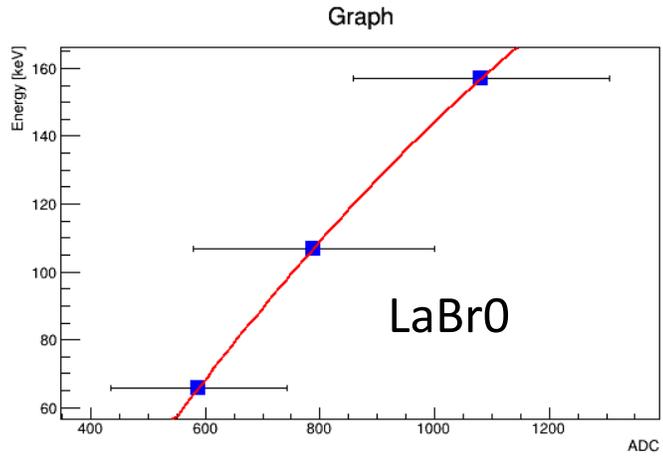

304 K case

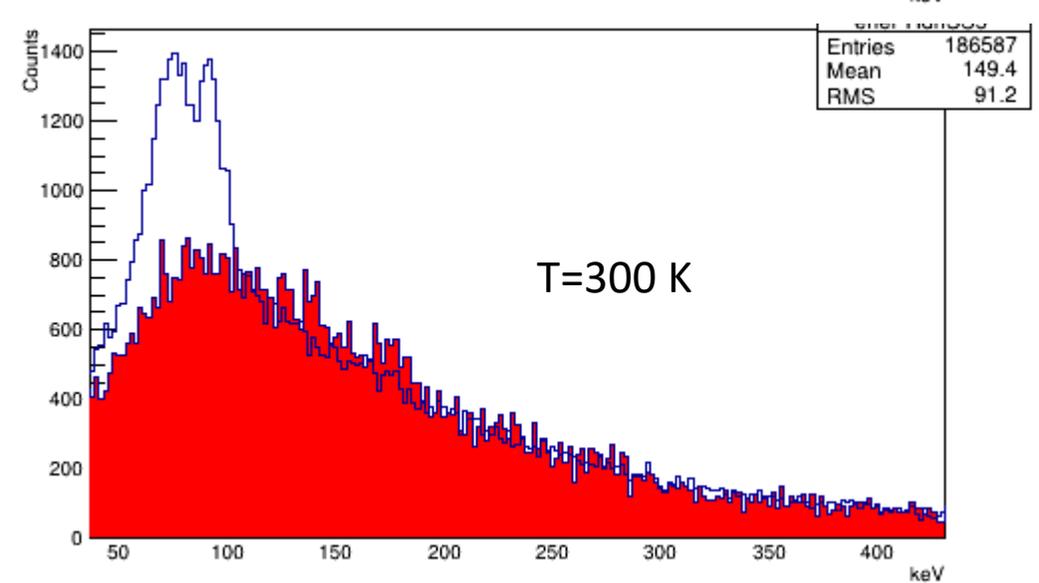

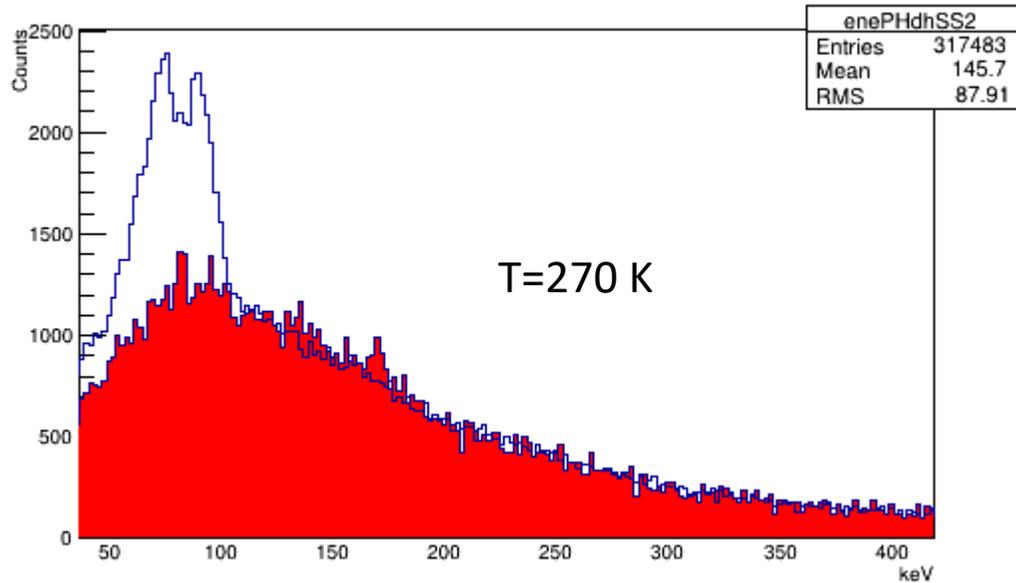

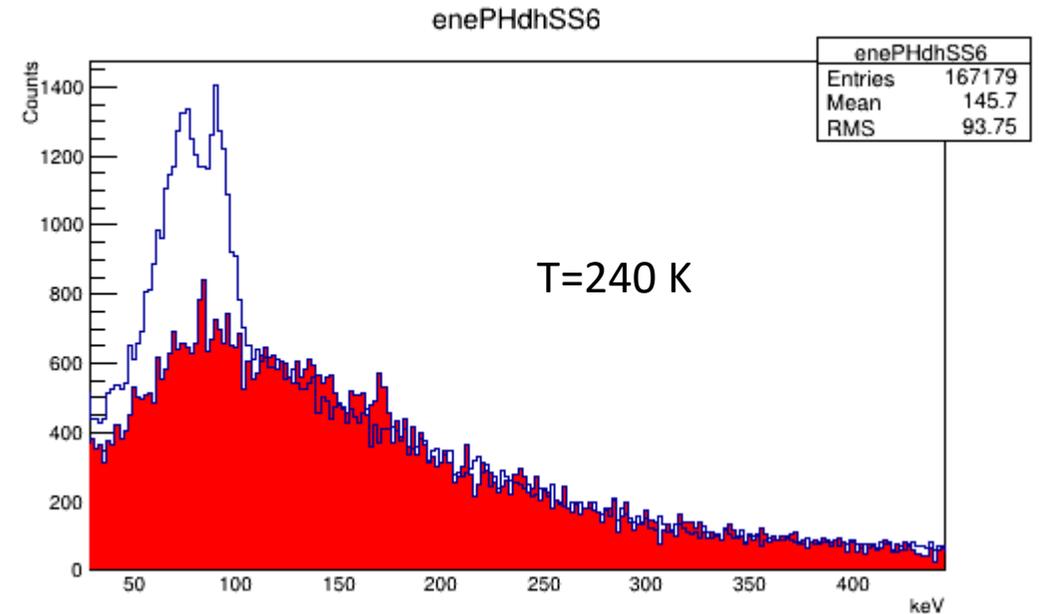

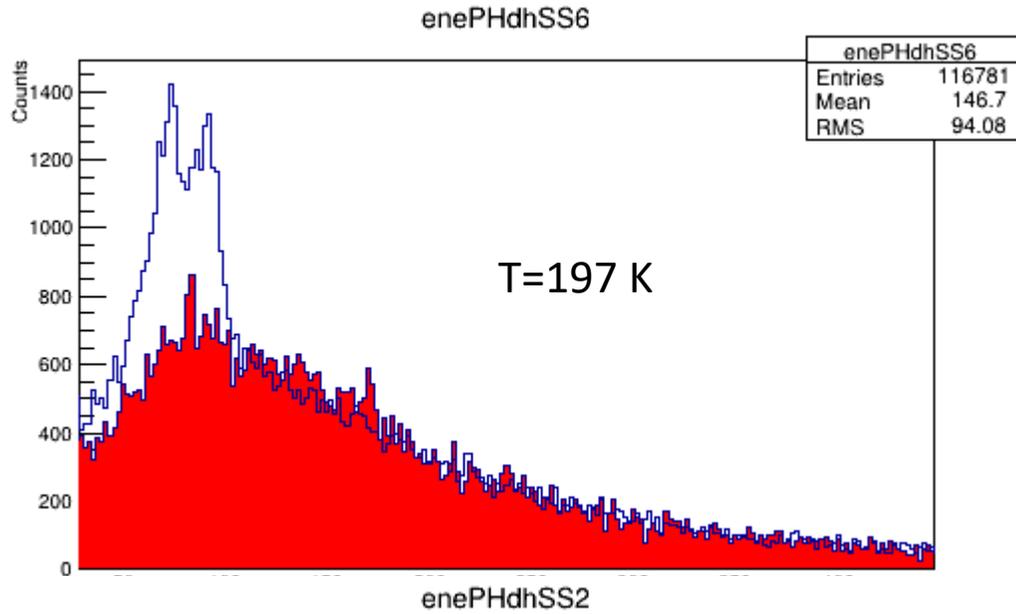

- Detectors 1 and 5 show a loss of efficiency at one of the cuts
- Detector 5 has inefficiency only at low energy
- Detector 1 has inefficiency also at higher energy so it had been excluded

Calibration curves

Detector 0 is excluded

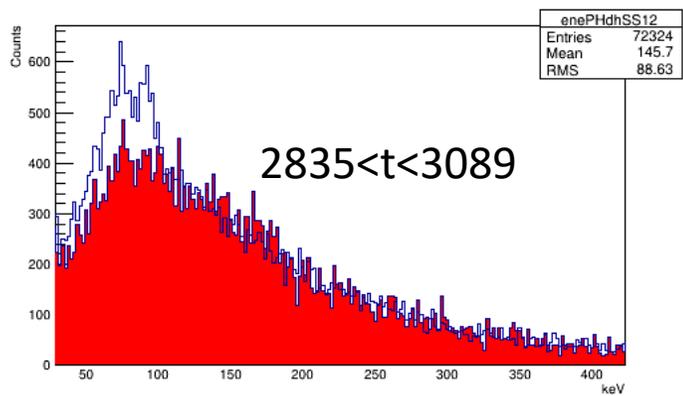

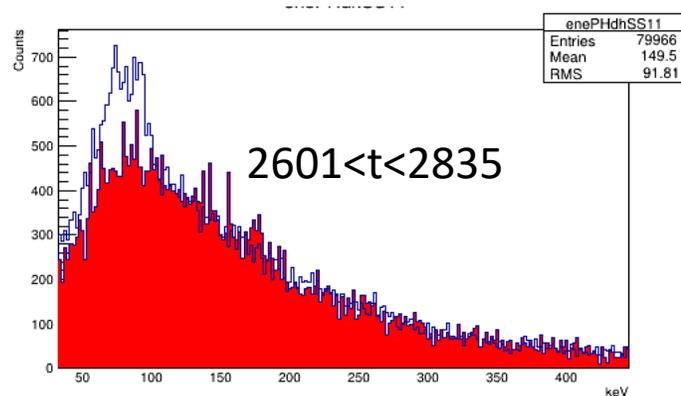

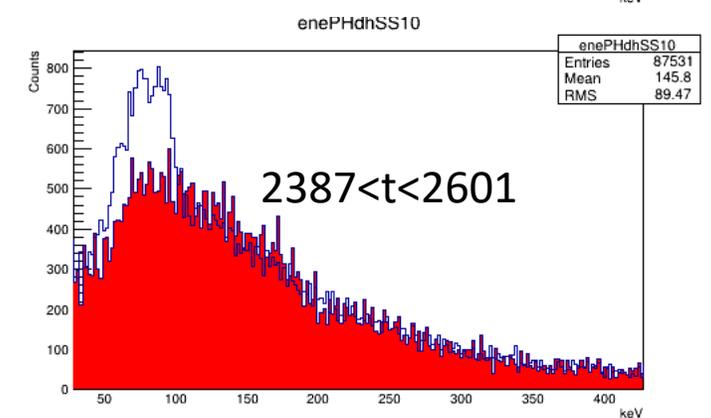

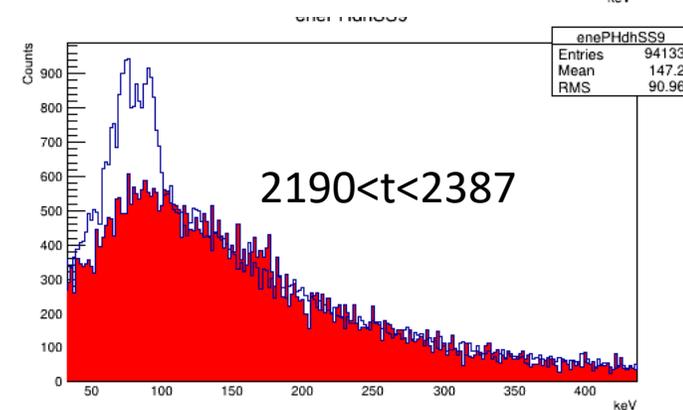

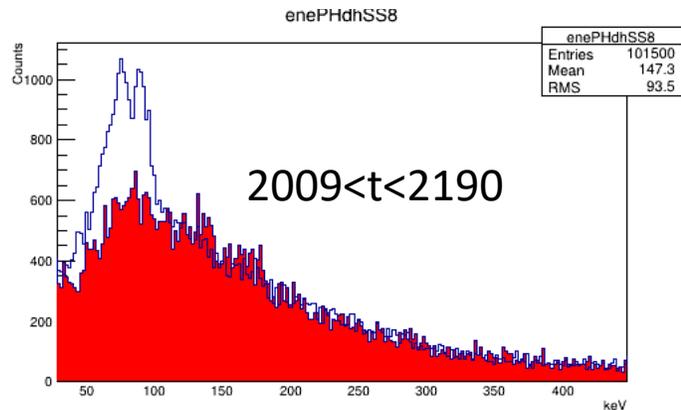

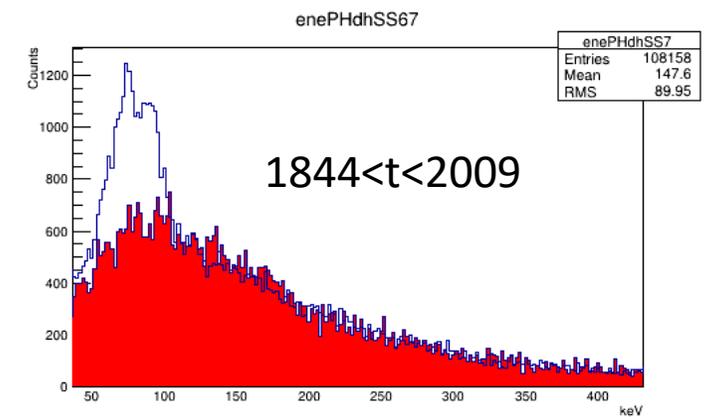

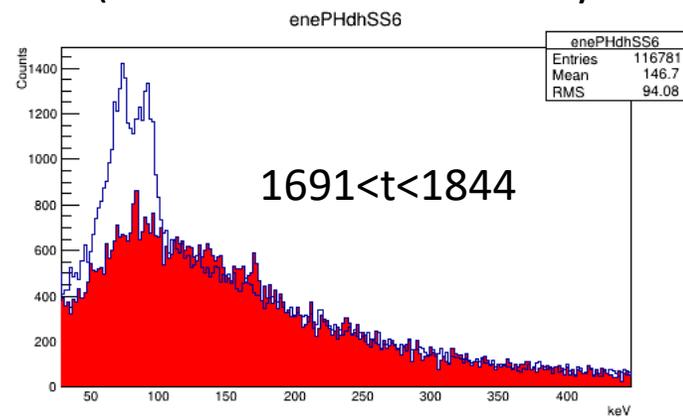

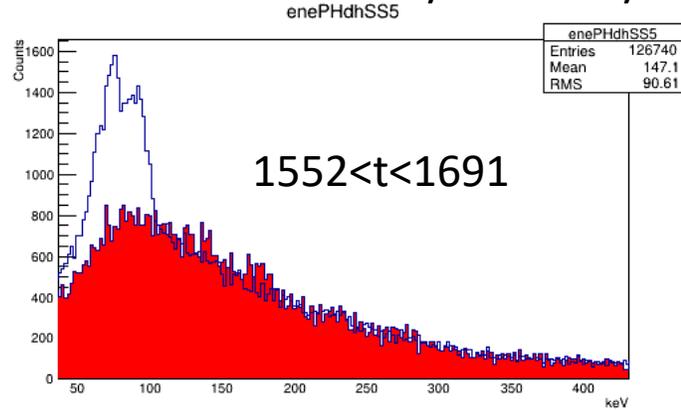

Time interval 2

Normalization: 200-400 keV

Time intervals at 197 K

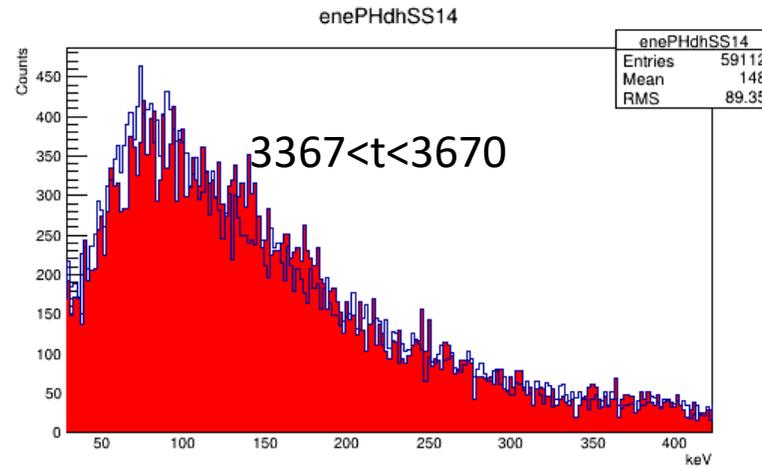

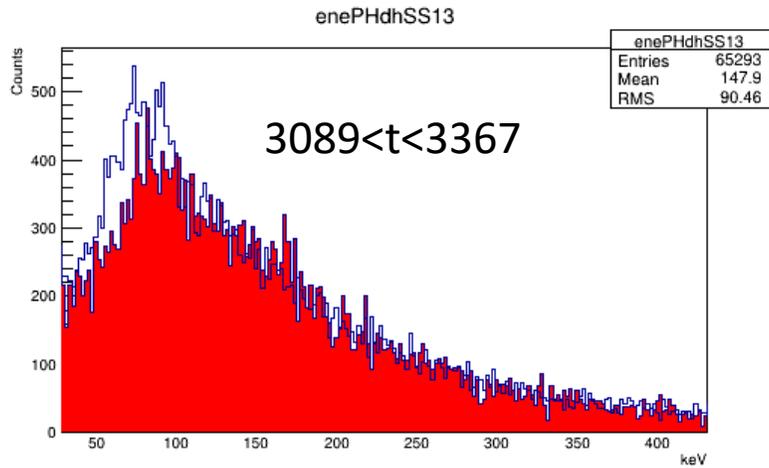

Distributions are corrected by efficiency and livetime (almost 100% in the delayed region)

— Signal+background
■ Background

Time intervals at 197 K

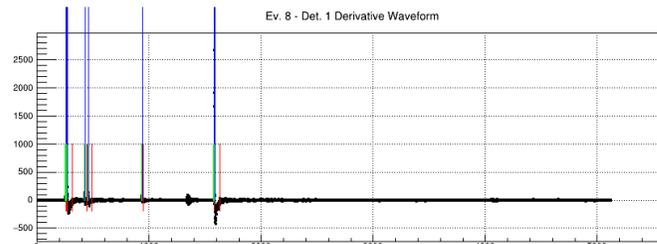

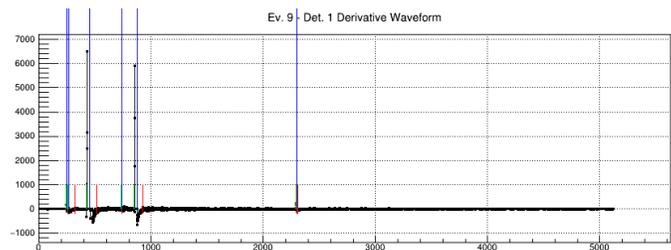

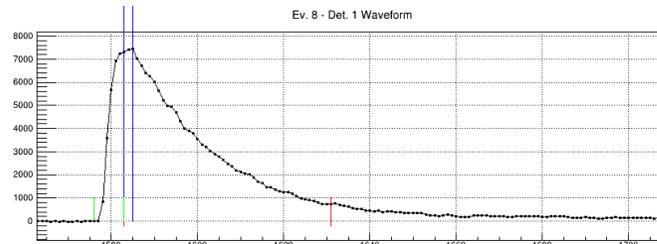

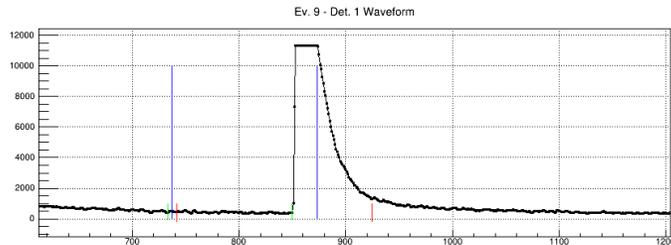

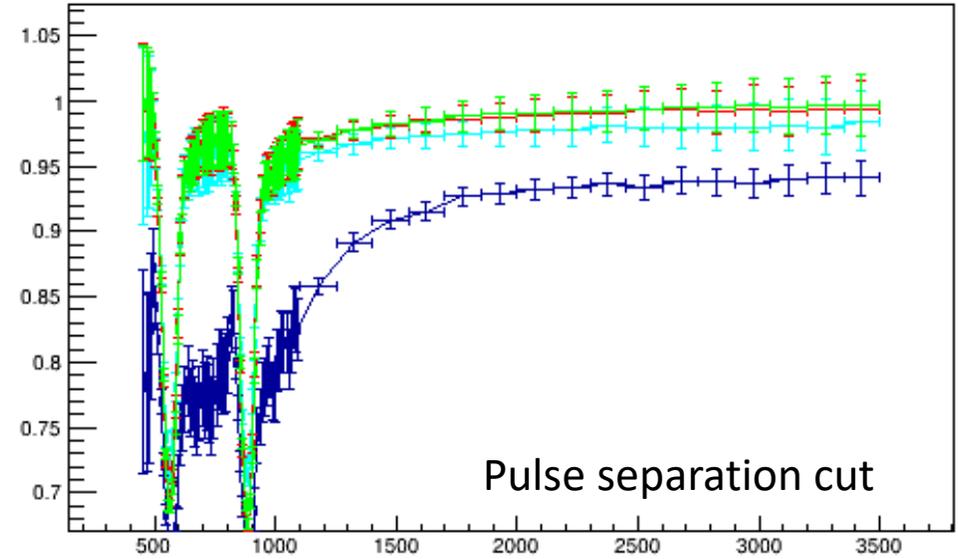

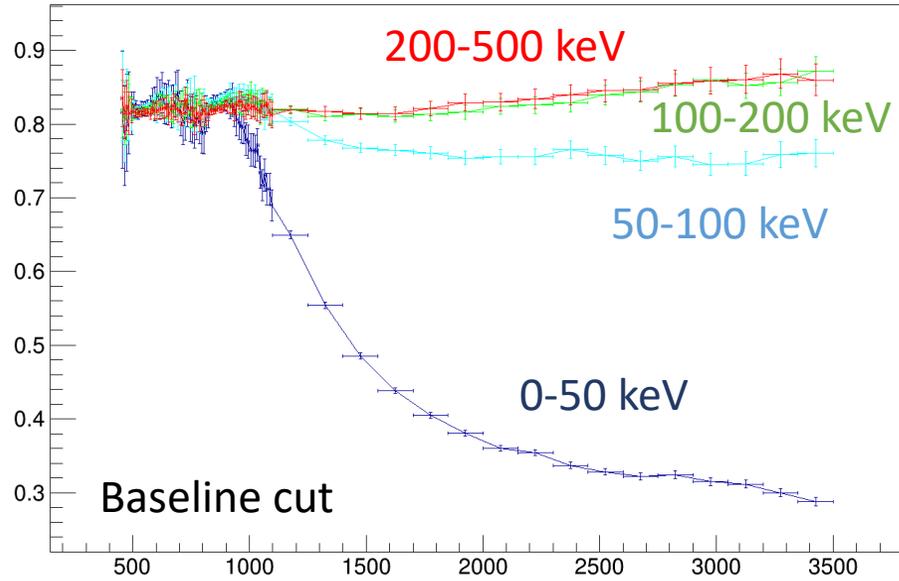

Distributions are corrected by efficiency and livetime (almost 100% in the delayed region)

— Signal+background
■ Background

Efficiency

Detector 1

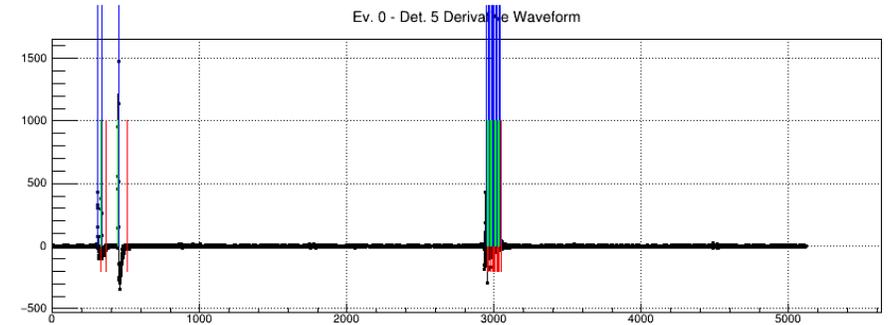

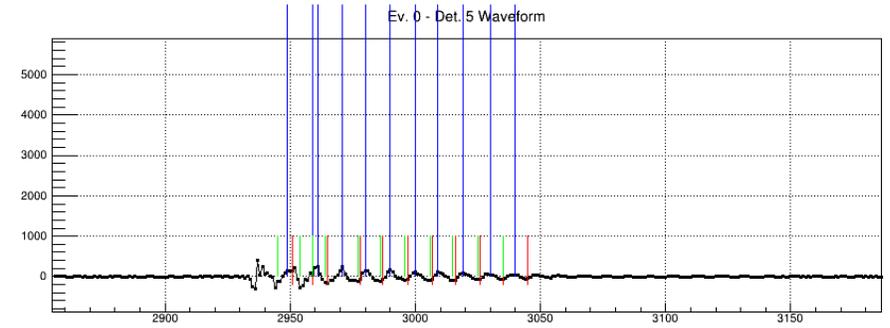

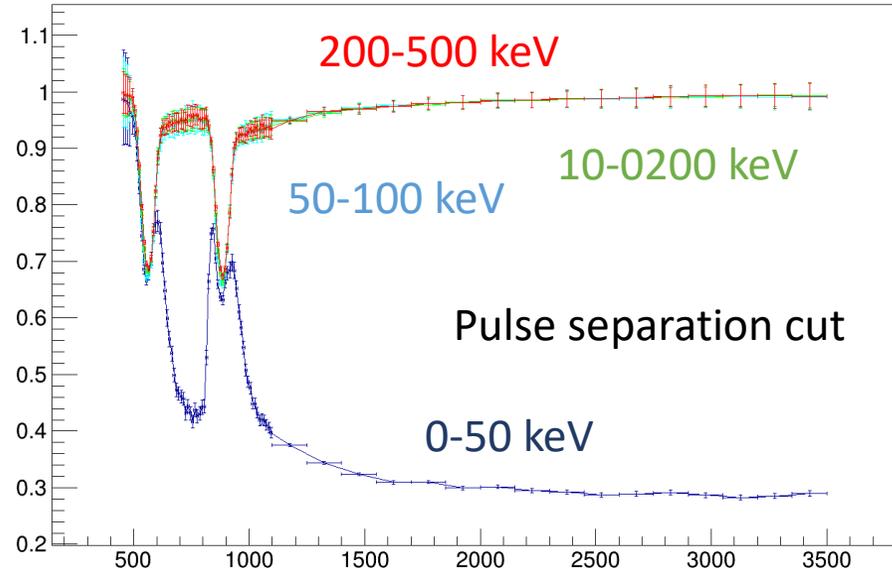

Double identification or background identified as signal

We decided to remove detector 1 from the analysis (loss of efficiency also in the 50-100 keV region)

Efficiency

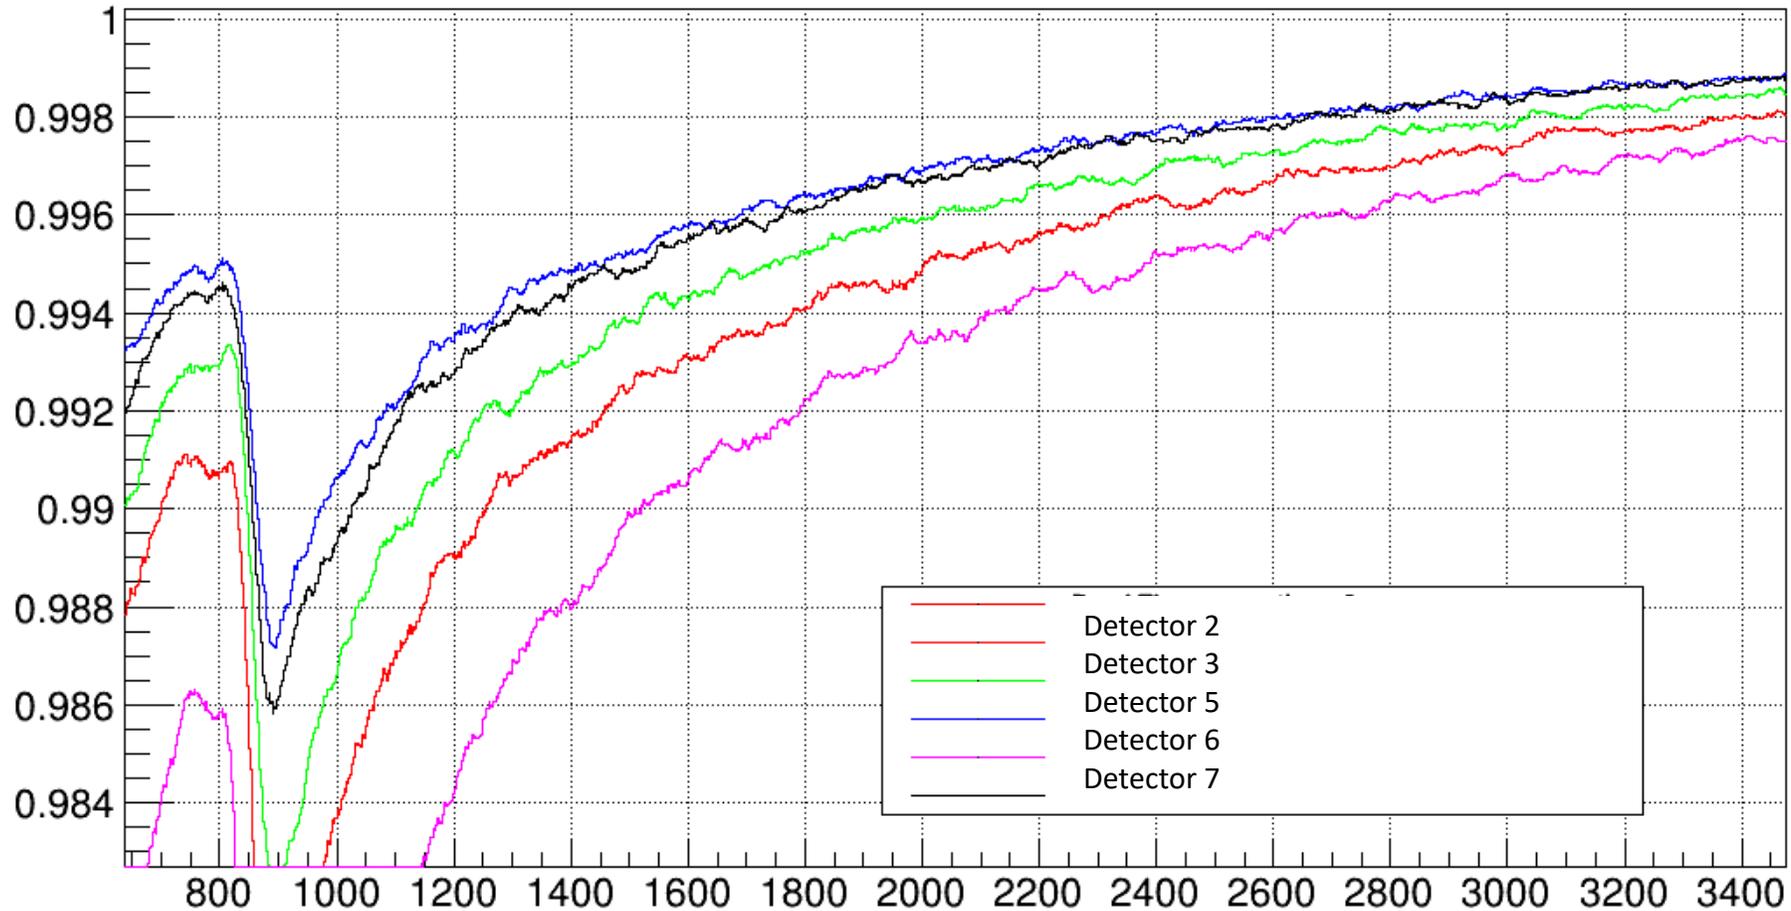

Detector 5

- Very frequent and several reconstructed pulses
- This does not affect signal (50-100 keV is fully efficient)

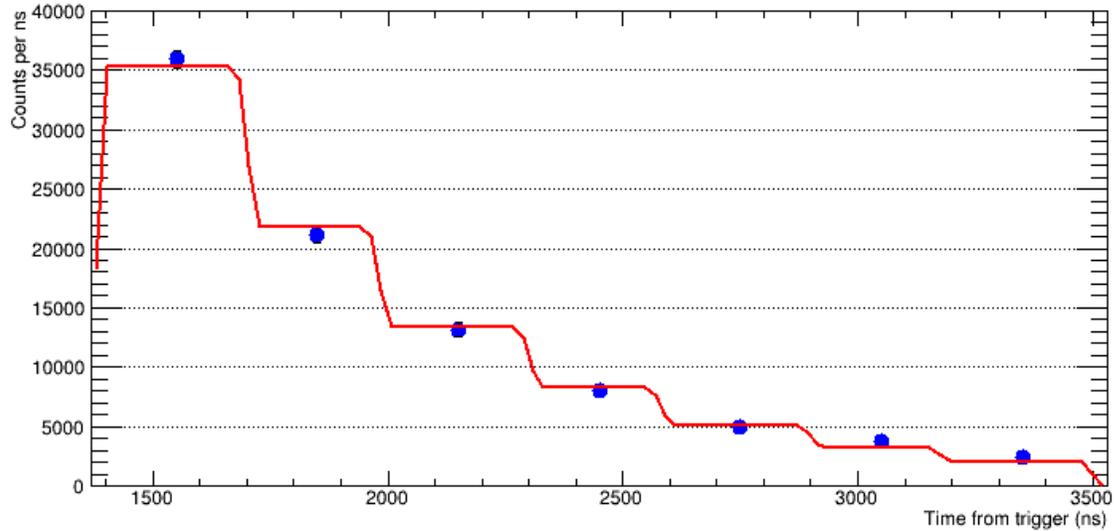

Livetime

Livetime always higher than 99% for all detectors in the time region selected for extracting the transfer rate to carbon

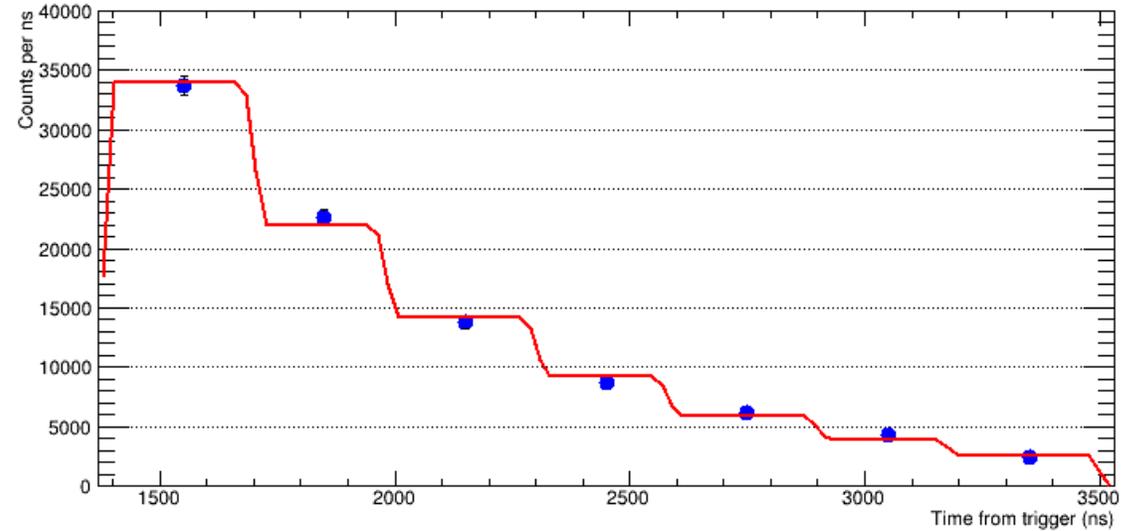

Counts per time interval

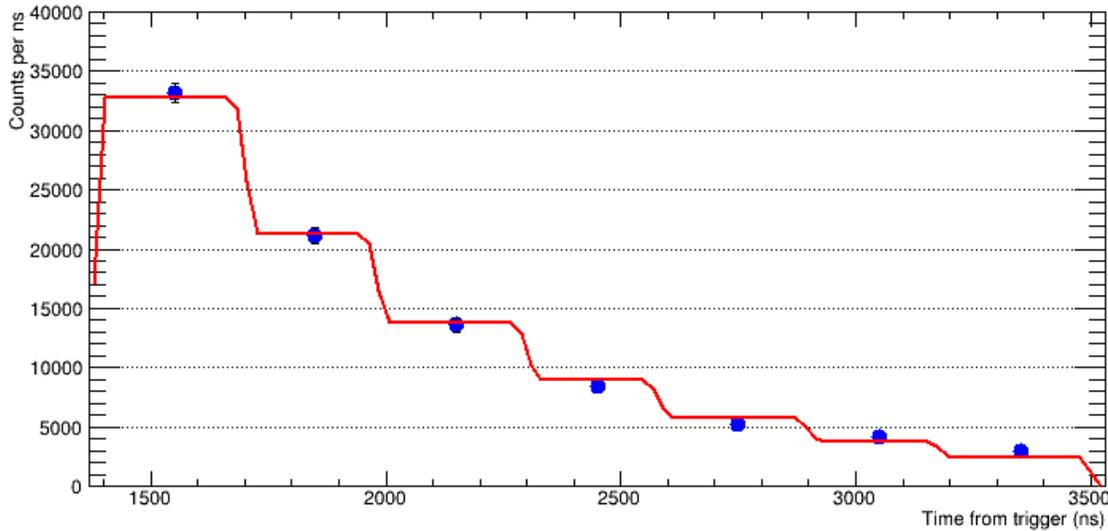

Delayed μ Z X-rays rate @ 197 K

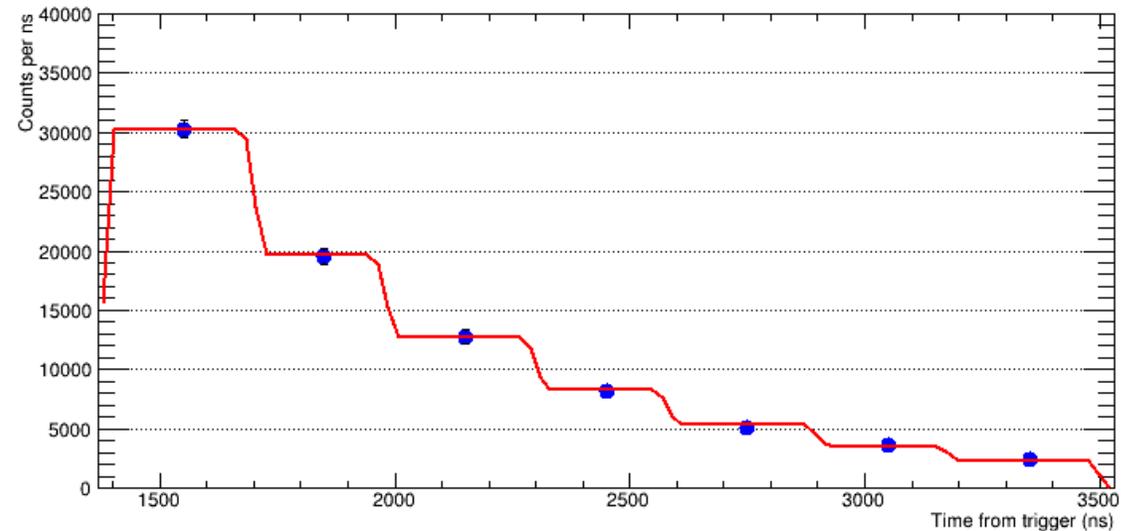

Delayed μ Z X-rays rate @ 237 K

Delayed μ Z X-rays rate @ 270 K

Delayed μ Z X-rays rate @ 304 K

Overview of next data taking

- The same procedure used for oxygen is repeated for the laser and no laser data samples
- The signal is the difference of the two integrals of laser and no laser data

Expected systematics

- Detector gain drift (expected 30 days acquisition time), change of the position of the peaks and consequently of the range of the integral;
- Detector efficiency
- Pressure of the target, a lower pressure means that less muons are captured and it affects also the transfer rate (ϕ parameter);
- Number of muons
- Laser energy stability, different probability of transition
- Length of the measurement;
